PRESENTED BY

COMMUNITER BONA PROFUNDERE DEORUM EST.

1

I have come before you gentlemen to deliver an introduction to the history of the late Dr. Benjamin Rush, on the institutes and practice of medicine, which I shall read during the ensuing winter. It is common on occasions like the present to give a history of the origin and progress of the branches of medical science to be taught, and to announce the plan of instruction contemplated in them. — The histories I will read have a value that will be best received by the entire study of them, and they have long possessed a ~~value~~ that under any abatement offered by the promulgation of their plan, at once disappears. — Nor will I occupy your time with the history of medicine. Such a history can propose nothing new, and offer no instruction that has not long

Additions to various
parts of this lecture —

Much has been said by pathological authors of venous and arterial congestions or plethora, the views I have given, will shew that a venous plethora cannot take place from mere rapidity of circulation, and can only arise from abstraction of the veins, or from the contraction of the universal areas of the arteries - where then the an arterial plethora can take place from the exertion of the tonicity of the veins, may require further observation —

A weak or strong action of the heart ~~and~~ or an abstraction of the large trunks of vein, ~~and~~ or arteries, cannot alter the flux of blood ~~and~~ thro' the circuit — for since that abstraction ~~and~~ is in the course of the circle, the obstacle ~~and~~

ago in some familiar to the youngest student
nor would I willingly be guilty of ~~containing~~^{2.}
~~and~~ mocking of your knowledge by repeat-
ing that which forms the preface to almost
every book in the sciences. - The historical
introduction and treatise so common in
our books and lectures, have always ap-
peared to me to be the mere apologies for
thought, the substitution of the worthless em-
ployment of transcribing, for the useful oc-
cupation of reflection. and even under the
most ingenious and eloquent forms in which
they can be presented, they seem like the
aeping up of time only for the purpose of
sacrificing it in ~~showing and proving~~
~~showing~~ ~~over~~ ~~their~~ ~~point~~, ~~but~~ ~~not~~ ~~confir-~~
~~that~~ ~~to~~ ~~know~~ ~~the~~ ~~history~~ ~~of~~ ~~the~~ ~~science~~ ~~so often~~

tion, opens the supply of blood to that
source (the heart) from which any plethora
caused by that obstruction, must proceed -
If the obstruction should be complete no more
could be sent on from the heart than the
contents of the ventricle, if the obstruction
be partial then, the blood will only take
on a velocity inversely proportional to the
diminution of area - The phenomena
afforded by a ligature around a limb afford
no proof of congestion taking place from
the obstruction of the large trunks, for here
the heart continues to be supplied from
other sources, and can therefore furnish
blood to the arteries for the congestion in the
tied veins -

The obstruction of the aorta furnishes
no argument against the power of the heart
to propel the blood through the body

power was confounded, and one oblique
was scattered over a wide bound on by
wind, so deposited on a emprise of the
airian, Clouds of opportunity and gathering
was as frequent when I left the University as
when I was first born. Next I hope to be
except the states and territories, but the
first object is not another branch of a foreign
school, as to the case of getting a common
of deposition in the form of the history of the
originals prop of Medicines -

Under these impressions it has always
appeared to me to be a desirable object in an
introductory lecture rather to enquire into
those subjects of our art that at ~~now~~ ^{Demand.}
igation, than to consume both time and
patience in framing conjectures on the
origin of medicine, or repeating quotations
of history long since established, and every

where to be found. But besides the advantage
probably resulting from such a plan of
procedure. There is an other reason with
me not less important. You know that
I propose to read to you the lectures of
an other. and tho' constantly in the practice
of offering remarks on those parts that seemed
to require further elucidation, and of guard-
ing my pupils against ~~over~~ ^{from} what ap-
pears doubtful in its nature or authority.
State my office precludes me from the opportunity
and the freedom of offering any extended
views of my own. - I am happy therefore to
embrace the occasion now occurring before
you, ~~to~~ to communicate the result of my ex-
aminations on the subject I have selected for
the present lecture. -

It was my intention to give you at this
time the result of some observations and re-
stations I had made on the Pulse, and

5. The knowledge of

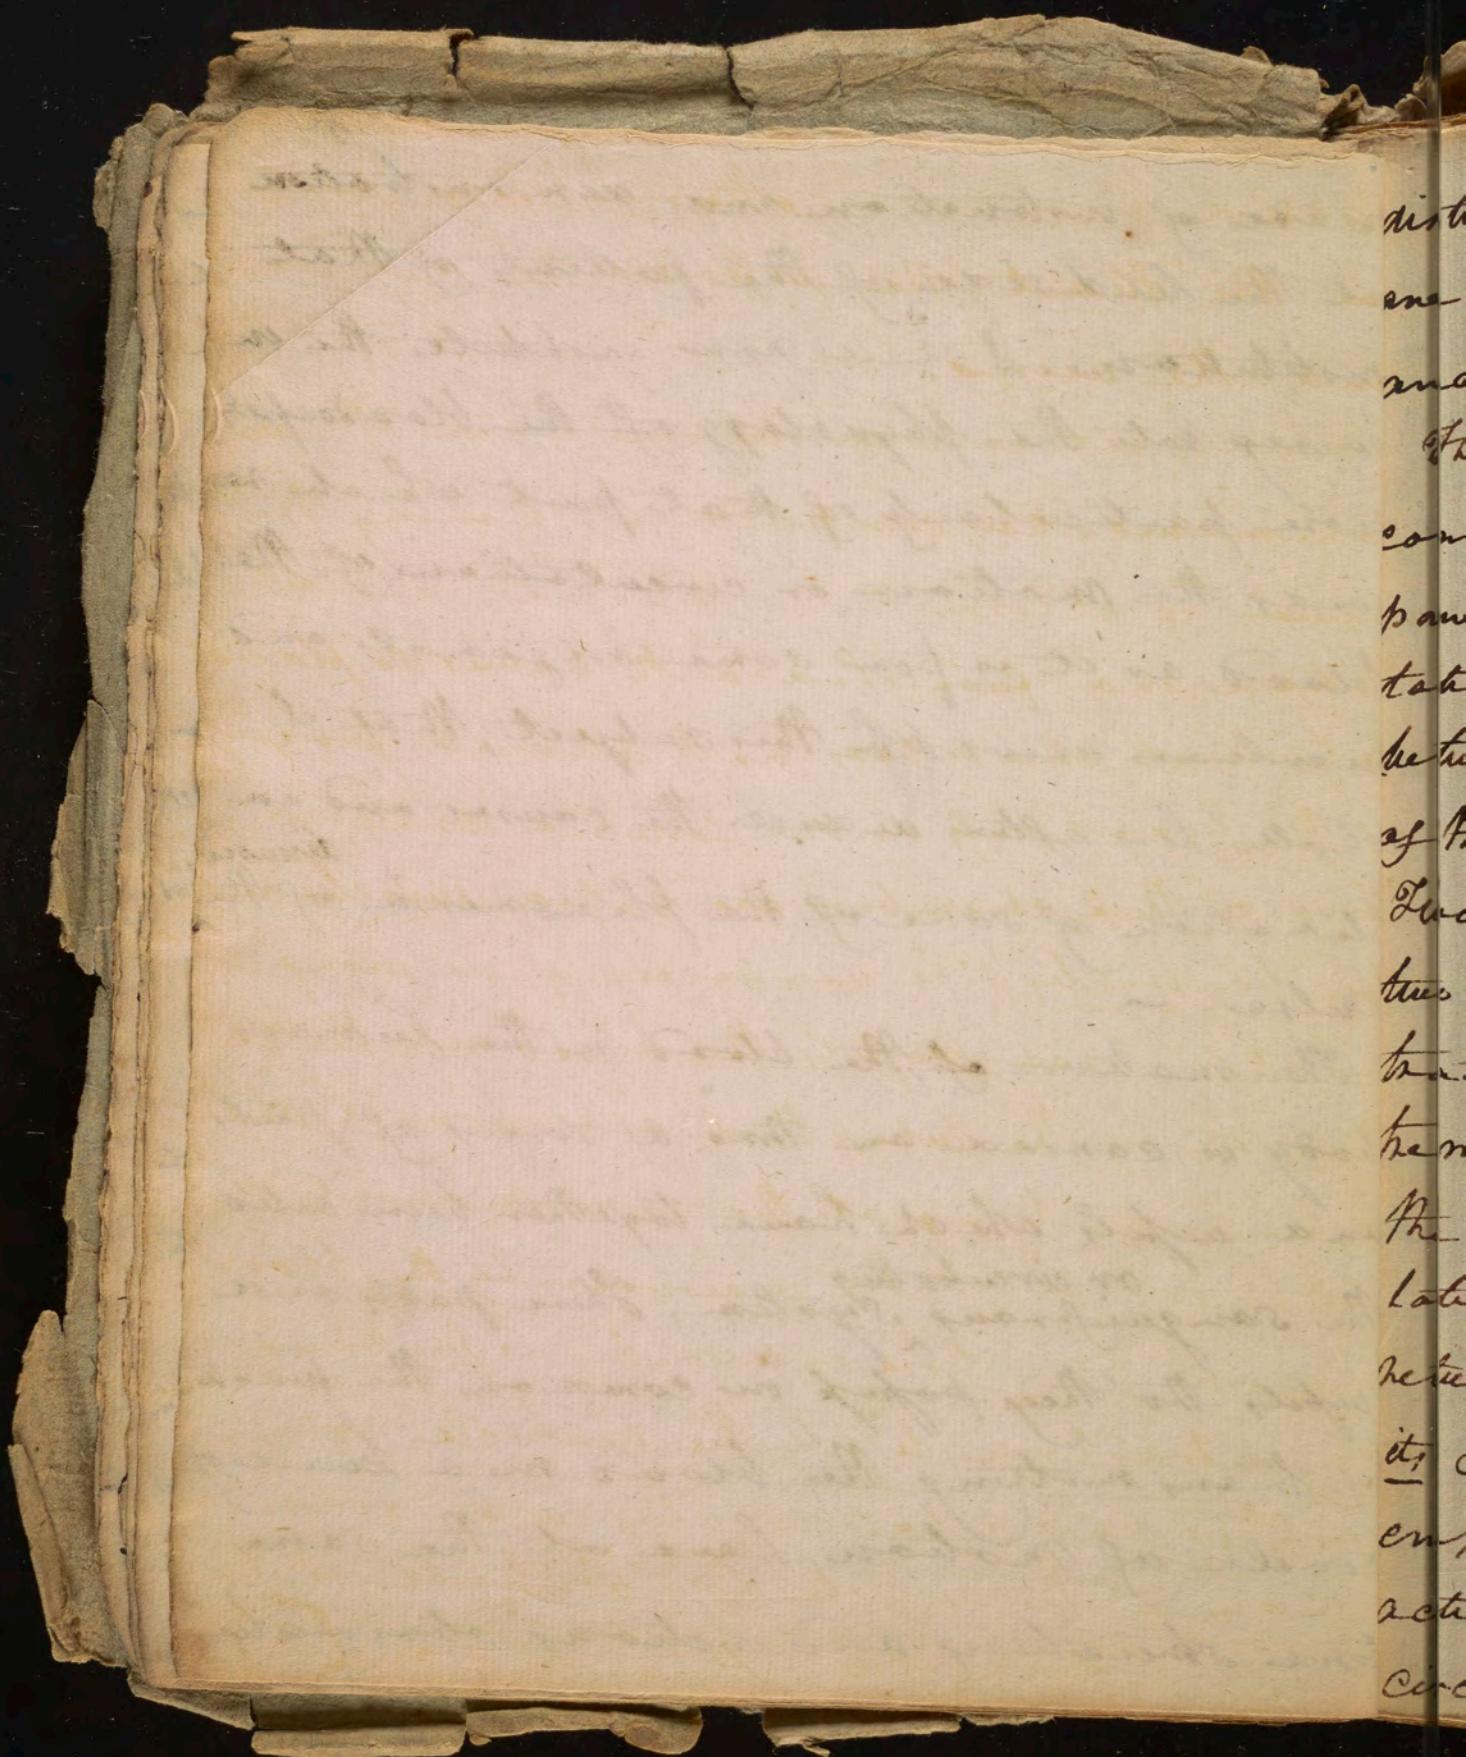

to apply the knowledge thus acquired to the explanation of some of the phenomena, and to the cure of disease. But you are aware that the various forms and modes of the Pulse, properly so called, are functions of the diseased Sanguiferous system - and since the diseased functions of this system are only alterations of its healthy action, it is plain that the healthy action of this system, or as it is commonly called the circulation of the blood should form the basis of an enquiry into the nature and causes of the diseased Pulse. - I will therefore ^{at present} defer the consideration of the Pulse as a symptom of disease, with the intention of laying before those of you who may attend the practice of the Philadelp. Am. house, the ideas and facts I may possess on this subject, either in the form of a Lecture, or in the more useful and impactive

5

Made of instruction and demonstration
at the bedside of the patient, of that
institution. I shall now institute the in-
quiry into the physiology of the blood, per-
more particularly of that part which re-
gards the motion or circulation of the
blood, as it is from some original and
peculiar views on this subject, that I
shall hereafter deduce the causes and ex-
plination of some of the phenomena of the
pulse. —

The motion of the blood in the human
body is carried on thro' a series of parts
and vessels which have together been called
the ^{or circulating} sanguiferous system. These parts and
vessels, tho' they possess in common the function
of transmitting the blood in a kind of
circle of motion, have at the same
time structures and actions obviously

distinct from each other. - These parts
are the Heart, the arteries, the capillaries,
and the veins.

The heart is a muscular organ of four
communicating compartments, having the
power of alternate contraction and dilatation, and furnished with valves so placed
between its chambers as to allow a progress
of the blood only in one forward direction. -
Two of these chambers are called auricles and
two ventricles. The ventricle by its strong con-
tractile force propels the blood into the ex-
tremities of the tubes that arise from it, whilst
the auricles being at the same moment di-
lated and filled as a reservoir by the blood
returning from those extremities, is prepared by
its contraction to fill the ventricle now
emptied and dilated. Thus by an alternate
action of the auricle and ventricle is the
circulation continually carried on. From

This view it appears that one auricle and ventricle placed in a part of the circuit of the blood's path thro' the body, would be sufficient apparatus for effecting the continual circulation, - and that a perfect heart required no more than these two divisions. Why then has the human heart four? To answer this question, it is necessary to remark that before the blood is fit to be conveyed as nourishment to the body by this single beat of one auricle and ventricle. it must in some places part with some of its component parts, and in others receive some new principle from without. - Thus the blood coming in contact with the external surface of the body and in flowing thro' the kidneys, throws off the perspiration and urine. - But the separation in these cases being made from a comparatively small portion of the extreme vessels, perhaps not their hundredth part, the circulation thro' these extreme vessels is easily carried on by this single

This image shows a single page from an antique manuscript. The paper is a light cream or beige color, heavily mottled with darker brown and tan stains, likely from water damage or age. The text is written in a cursive hand, which is very faded and difficult to decipher. It appears to be organized into several paragraphs, separated by small indentations. The right edge of the page is very irregular, showing the torn and stained remains of the paper's original binding. The left edge shows the thickness of the book's pages. There is a small, distinct red mark or stain near the bottom left corner of the page.

9

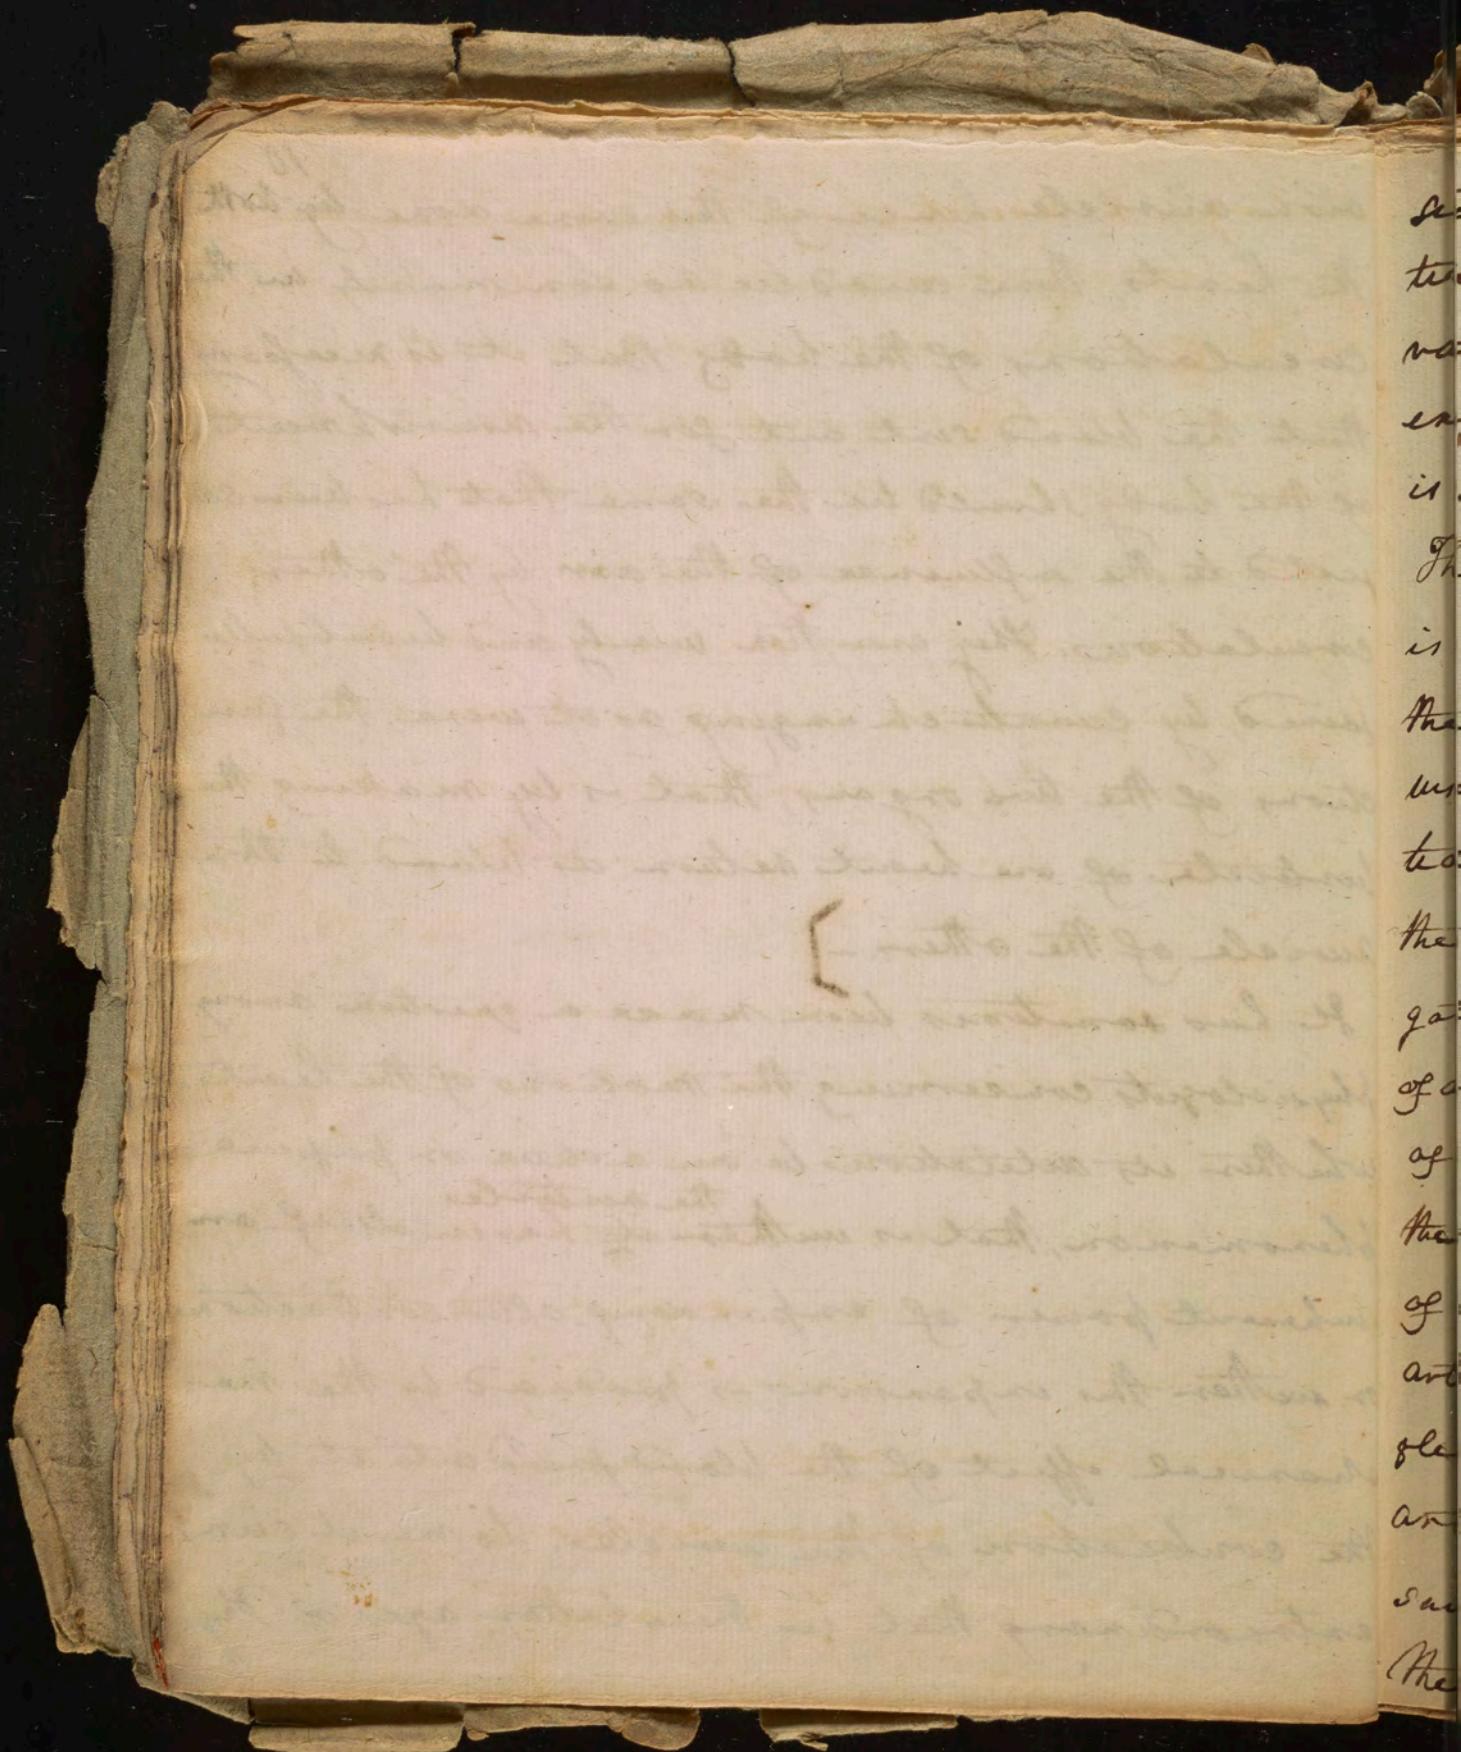

heart, without the aid of any new function or force. - But it is different in the case of the blood receiving a new principle from without. It is a condition of the circulation that the blood shall receive some new principle from the air, and not only that a small part, but that the whole mass shall, in a given time, be subjected to its influence. - This requires that the blood be sent thro' an infinite number of small vessels spread on the air cells of the lungs. From this extensive surface of friction a resistance is created, not much less than that which arises from the blood sent thro'out the body by the single heart. - hence then the necessity of a second auricle and ventricle or of an other heart to carry on this second circulation. - It may be interesting to point out the wise economy of their being thus joined together. - In a single heart as we have been considering it, the ventricle was supposed to return the blood to its

own auricle, hence if this were done by both the hearts, there could be no community in the circulation of the body. But it is necessary that the blood sent out for the nourishment of the body should be the same that has been subjected to the influence of the air by the other circulation. They are then surely and beautifully joined, by counterchanging as it were, the functions of the two organs, that is by making the ventricle of one heart return its blood to the auricle of the other. - }

It has sometimes been made a question among physiologists concerning the motion of the heart, whether its agitation be an active or passive phenomenon, that is whether ^{the ventricle} it has in itself an inherent power of expanding, after contraction or whether this expansion is produced by the mechanical effect of the blood pressed into it by the contraction of the auricle. To me it seems extraordinary that in these latter ages of Phys-

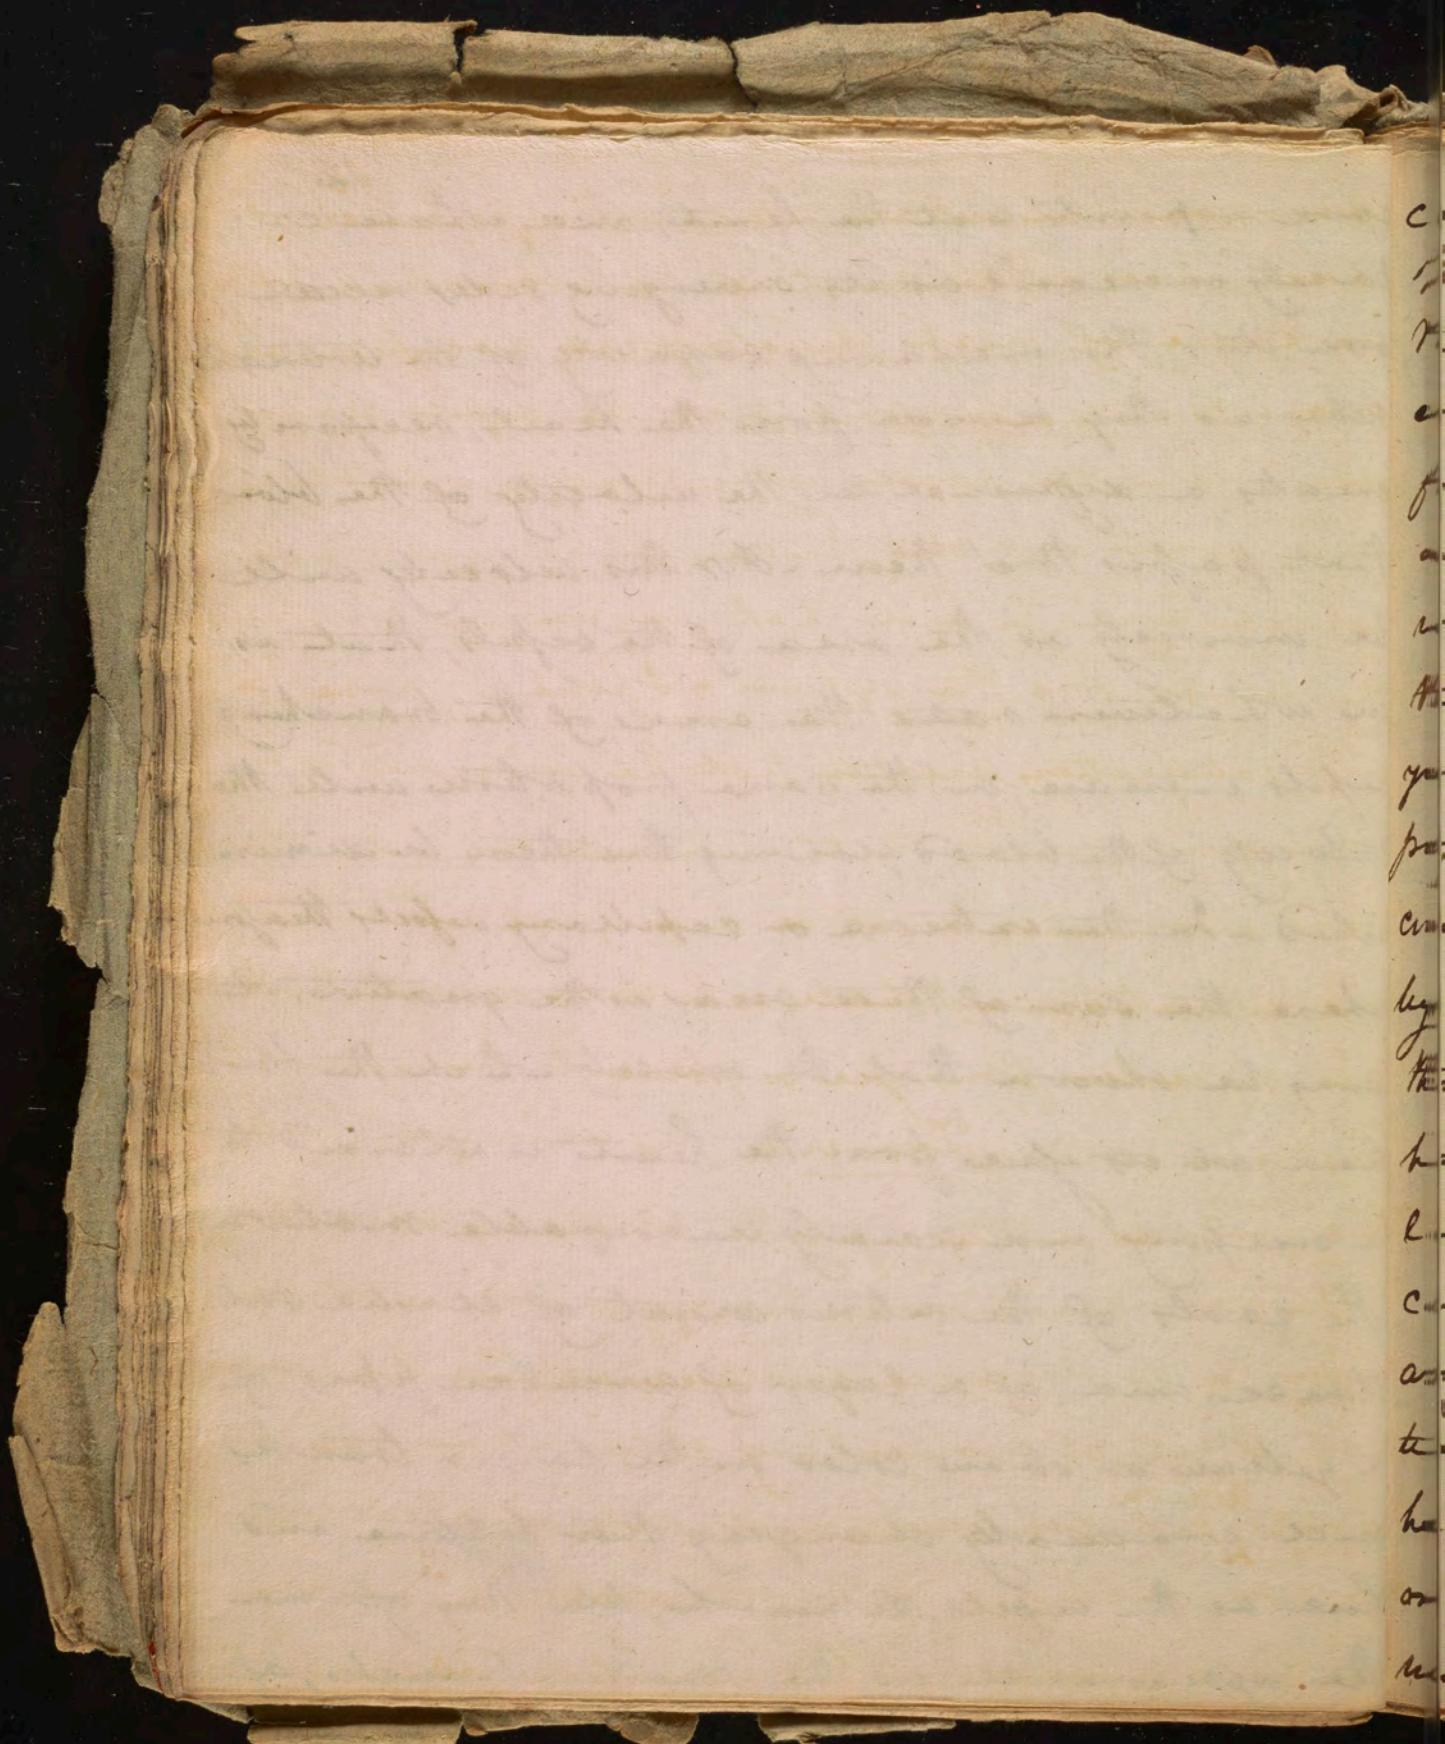

siology a doubt should exist, since the con-
tinuance of motion in the heart when sepa-
rated from the body and vessels of some animals
experimentally demonstrates that the ventricle
is actuated by a power residing in itself. —

The second part of the circulating structure
is the arteries. They are tubes arising from
the ventricle of the heart. that run into di-
visions and subdivisions, till they are distribu-
ted in their finest or Capillary branches, throughout
the whole body. — It can be shown that the aggre-
gate areas of the subdivisions of any one branch
of an artery is much greater than the single area
of the sections of that branch, and consequently
that the sum of the areas of a transverse section
of all the capillaries or extreme branches of the
arteries, must be greater than that of the sin-
gle tubular tube as it leaves the heart. The
arteries therefore ~~are~~ ^{in their form} said to resemble a tree whose, springing from
the heart, and in their contents, a cone whose

apex or point is at the heart, and whose capacity increases as its diverging sides recede from it. - This increasing capacity of the arterial tubes as they recede from the heart, necessarily creates a difference in the velocity of the blood that passes thro' them. - For this velocity will be inversely as the area of the vessels, that is in whatever ratio the areas of the branching vessels increase, in the same proportion will the velocity of the blood flowing thro' them be diminished. - In the extreme or capillary vessels therefore where the sum of these areas is the greatest, it may be shown that the velocity which the blood had at its issue from the heart is retarded to a creeping and scarcely measurable motion. The coats of the arteries consist of elastic substance, and of a layer of circular fibres, of a yellow or straw color in the larger trunks and gradually changing their texture and hue as the vessels diminish, till they assume the appearance in the smaller branches, of

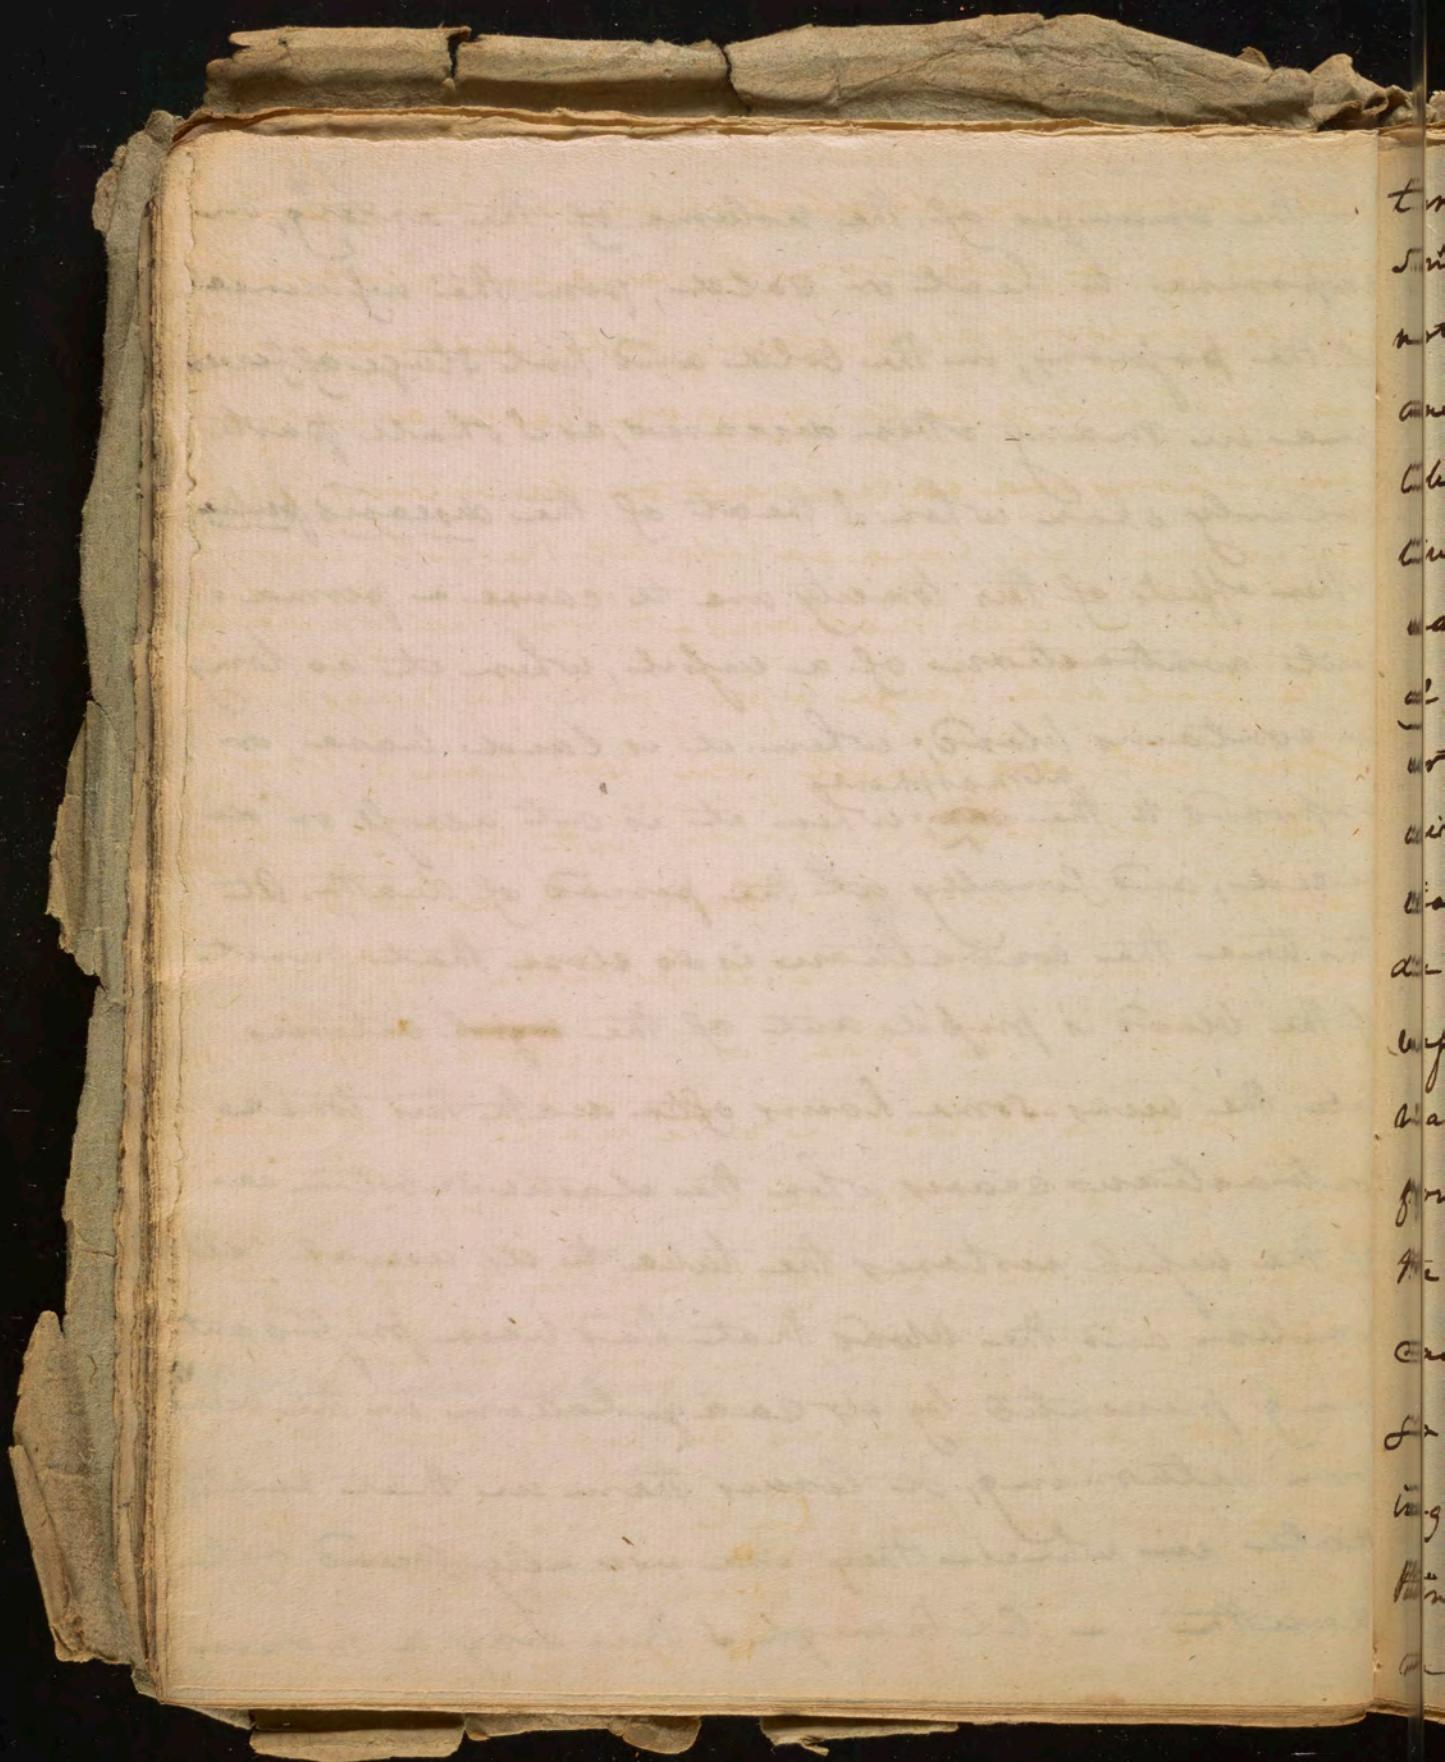

13

common muscular fibers - The presence of
these fibers in the coat of the arteries has been
the cause of much physiological discussion and
error - as it was inferred that the vessels derived
from them the power of alternate dilatation
and contraction similar to the heart, and
which served to aid that organ in propelling
the blood thro' the system - I hope to prove to
your satisfaction hereafter that the arteries do not
possess such power; that if they did possess it, the
circulation would not be aided, but obstructed
by its operation - I shall only remark here that
these muscular fibers give a power to the vessels wh-
has been call'd Tonicity - This tonicity or muscle
power
produces in the vessels the following effects - It
causes a variation in the size or volume of the
artery, by its increase or decrease, ^{and} this varia-
tion is not of momentary alternation like the
heart's ^{action} but continues in its state of enlargement
or contraction for hours ~~days~~ and even
weeks ~~months~~ duration. This variation is exhibited

or by their values. -

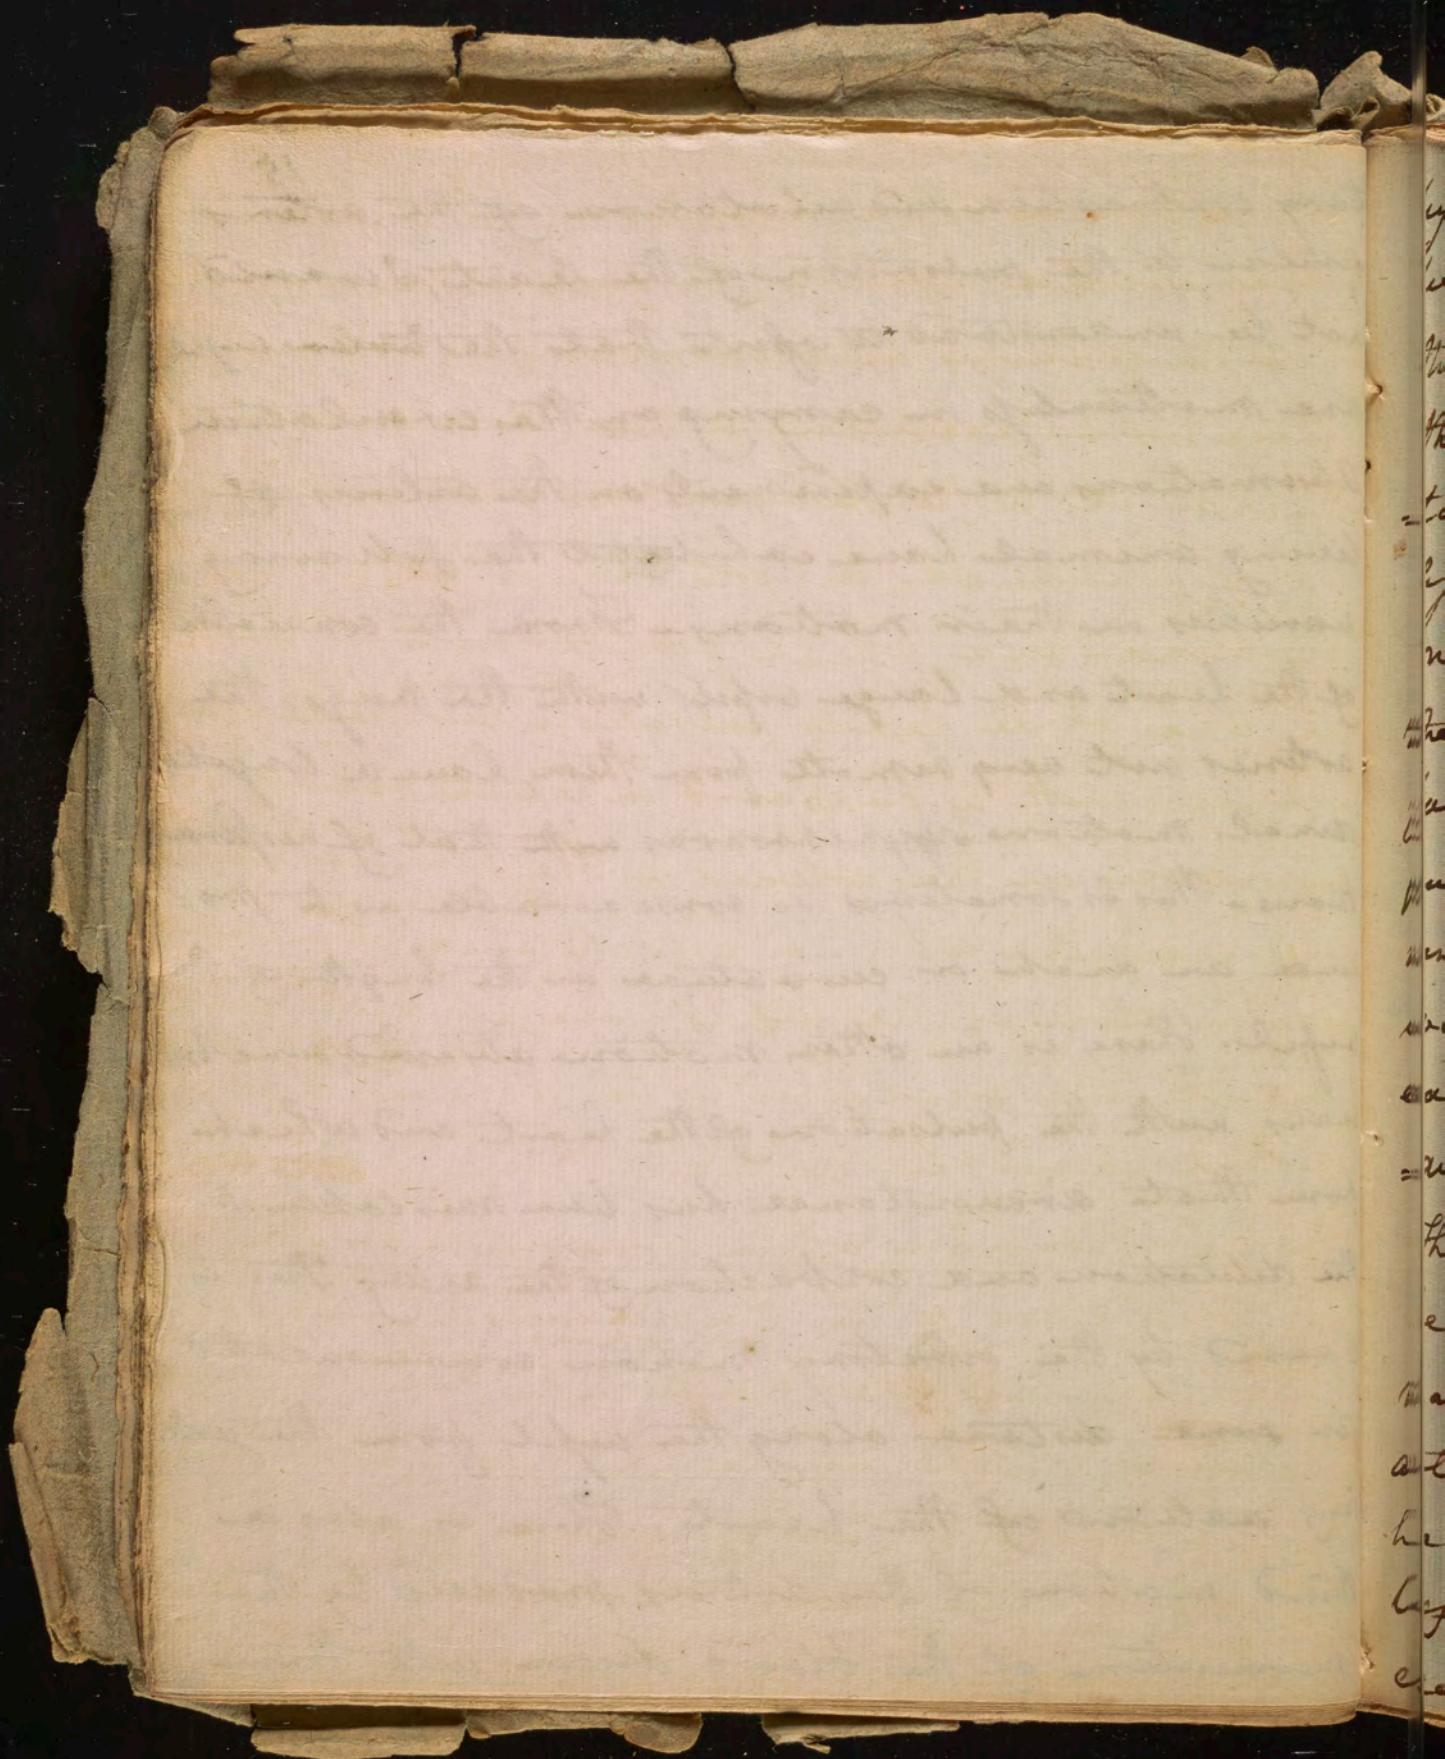

14

in the changes of the volume of the arteries, on exposure to heat or cold, from the influence of the passions, in the cold and hot stage of fevers and in many other diseases, as I shall particularly shew when I treat of the diseased pulse. Other effects of this tonicity are to cause a permanent contraction of a vessel, when it no longer contains blood; when it is laid bare, or exposed to the ^{atmosphere}; when it is cut across or divided, and finally at the period of death. At this time the contraction is so close that most of the blood is prop'd out of the ~~vessel~~ arteries into the veins. Some hours after death this tonic contraction ceases, when the elastic substance of the vessel restores the tube to its usual diameter, and the blood that had been prop'd out being prevented by its coagulation in the veins from returning, it leaves them in that empty state in which they are usually found after death. — Although I thus deny a moment

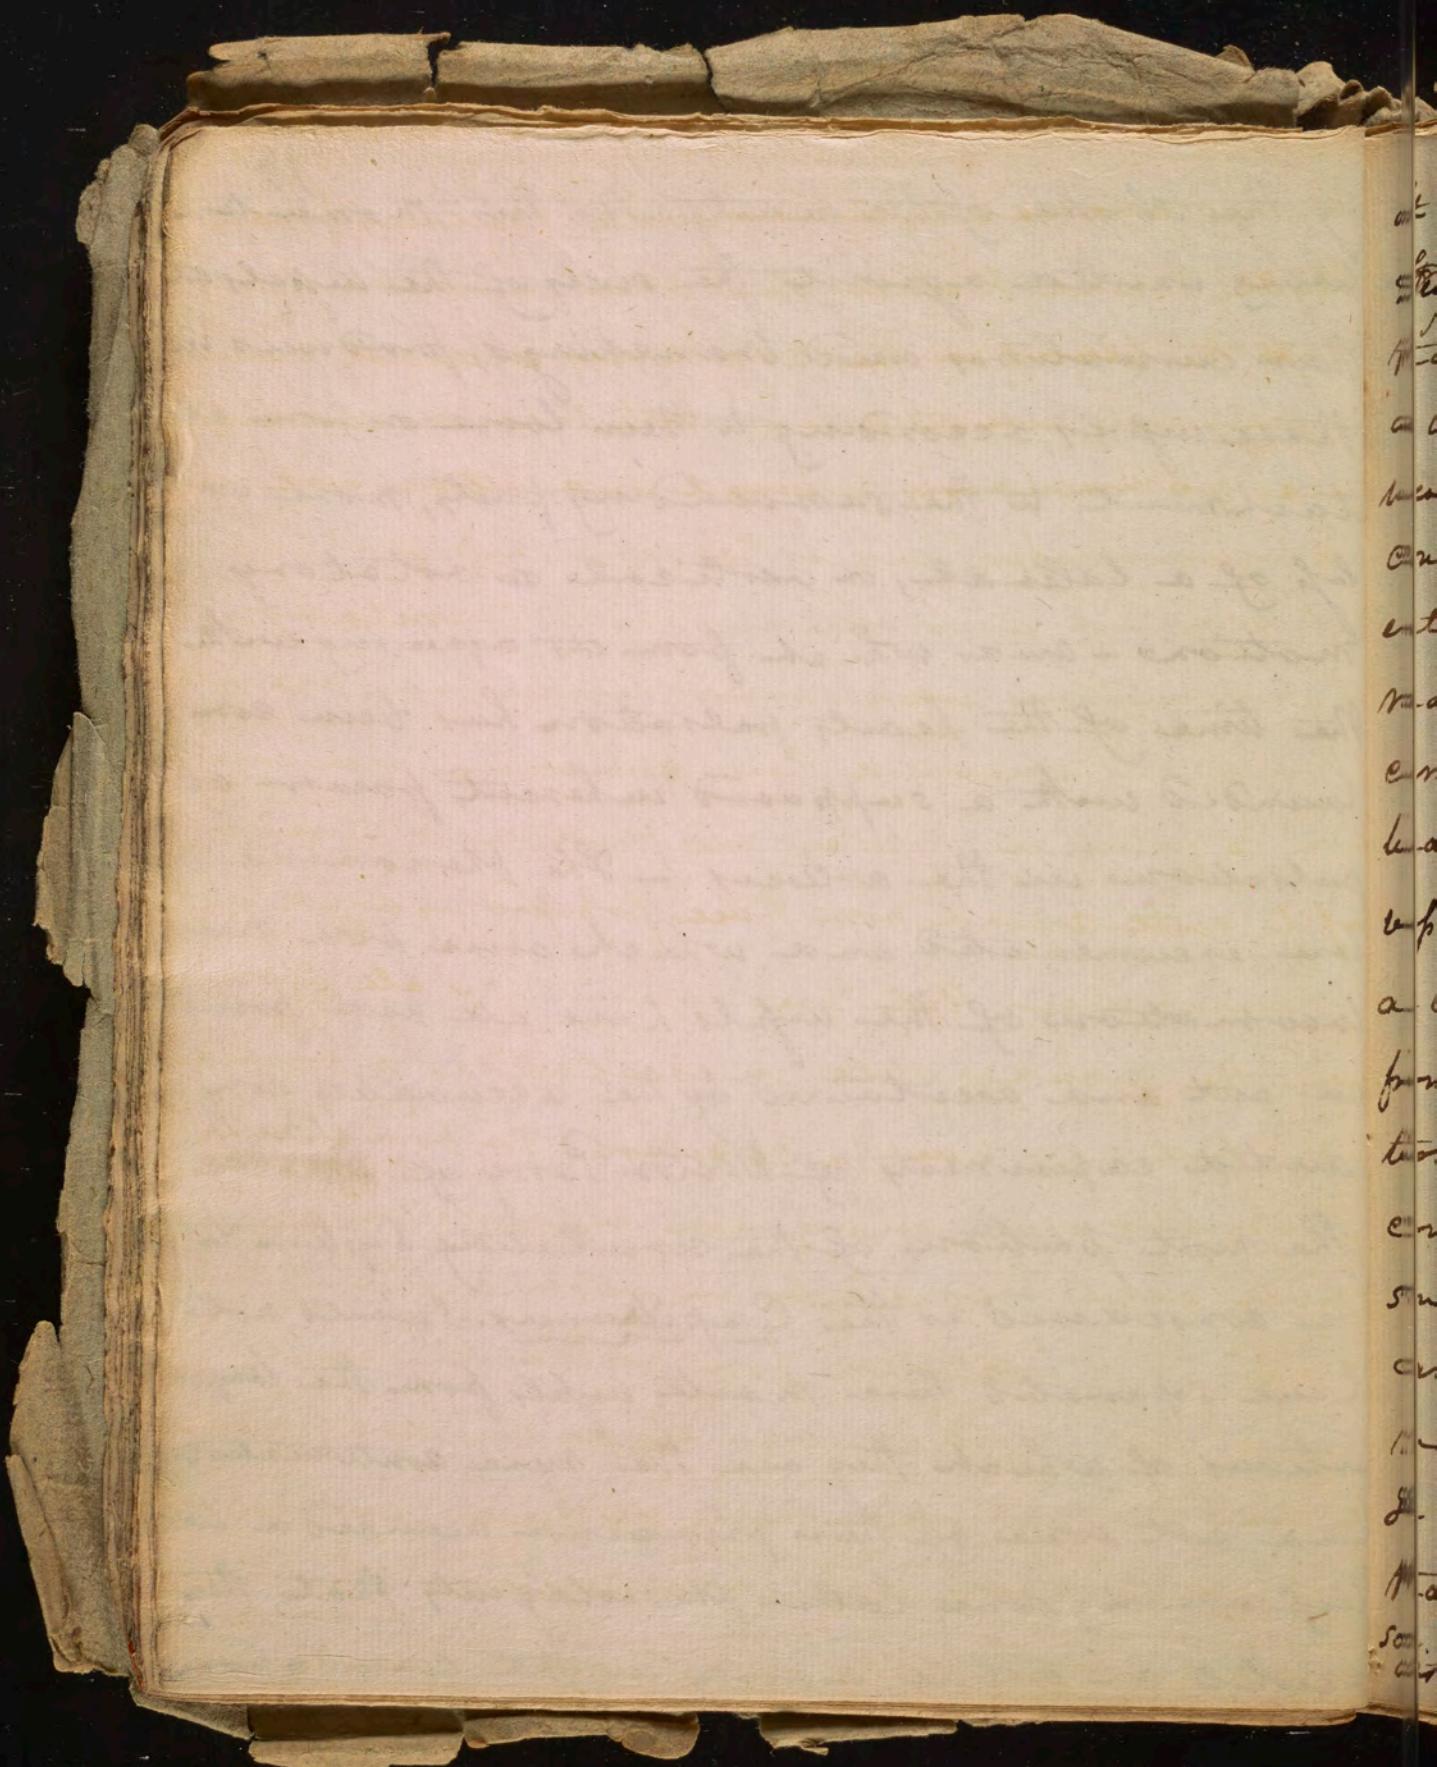

15

tary contraction and dilatation of the arteries similar to the pulsation of the heart, I would not be understood to assert that the arteries might not be instrumental in carrying on the circulation. Observations and experiments on the arteries of living animal have exhibited the following varieties in their motions. - From the connection of the heart and large vessels with the lungs, the arteries not very remote from them, have a longitudinal motion synchronous with that of respiration. - This is sometimes so considerable as to produce an arch or curvature in the length of the vessel. There is an other motion observed, synchronous with the pulsation of the heart and which from that circumstance has been mistaken for the dilatation and contraction of the arteries. This is caused by the vibratory motion communicated for some distance along the vessels from the jerking action of the heart. There is also a third motion of the arteries produced by the momentum of the blood driven into them.

by the stroke of the heart. For this momentum
being exerted against the sides of the vessels at
their curvatures and branchings, produces in
these vessels, according to their loose or firm at-
tachment to the surrounding parts, more or
less of a lateral, or vertical or rotatory
motion - and which from its agreeing with
the time of the heart's pulsation has been con-
founded with a supposed inherent power of
pulsation in the arteries. - The phenomena
here enumerated, and which arise from mere
locomotion of the vessels, have all been point-
ed out and ascertained by the accurately con-
ducted experiments of Doctor Parry of Bath -

The next portion of the circulating System to
be considered is the Capillaries. I would not
have separated these minute vessels from the larger
arteries of which they are the mere continuation
had not some of their phenomena induced a be-
lief among some later physiologists that they
exerted an active agency in the circulation.

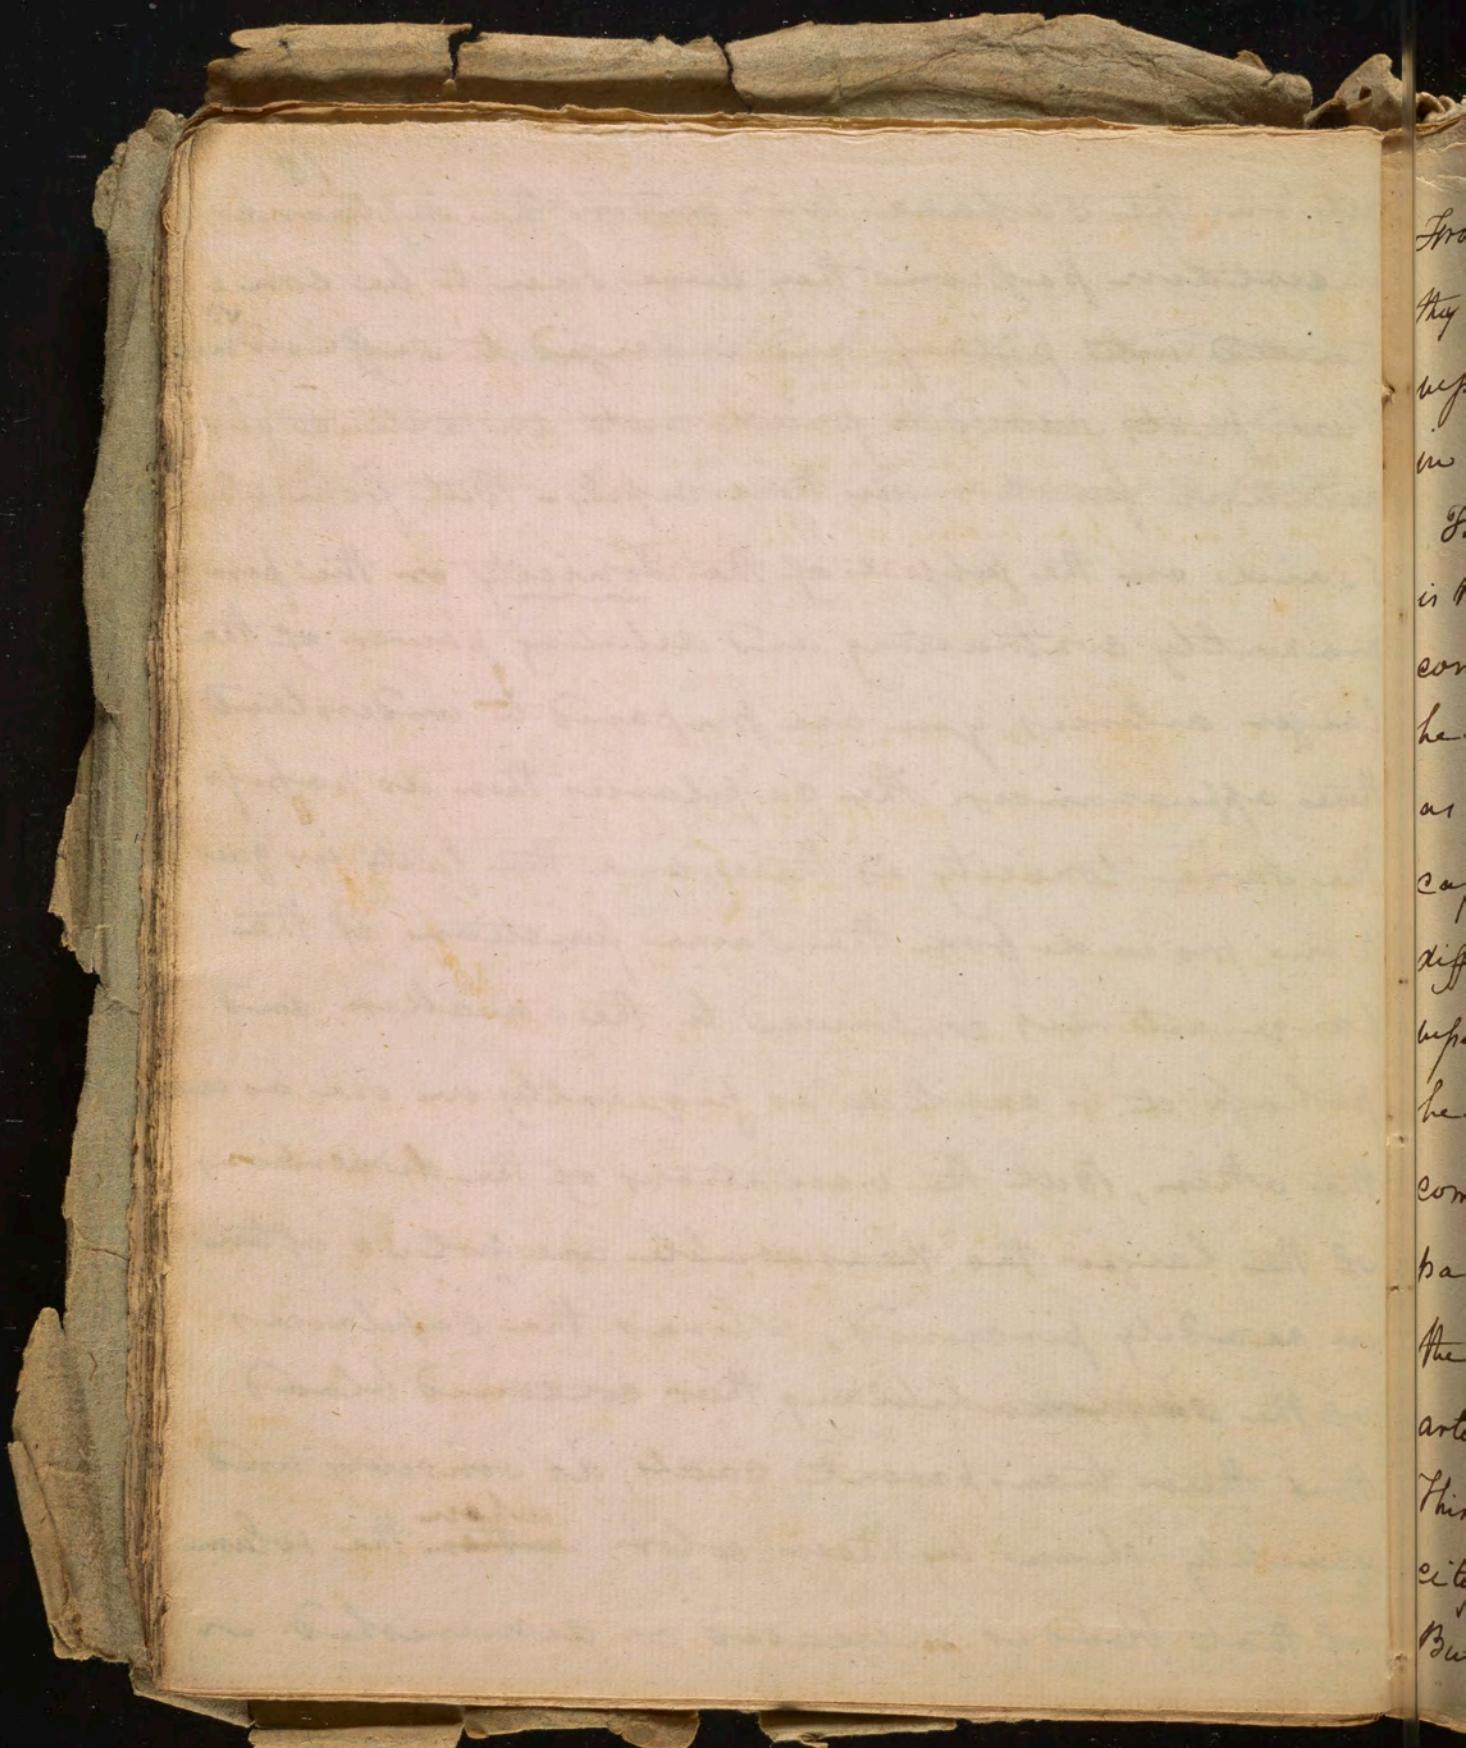

17.

It was observed by Lewenhook, Baglivi, von
Hegel, Senac, Haller and other experimenters
that the blood in the capillaries did not pursue
a uniformly direct course, but that its currents
were promiscuously forward and retrograde in
contiguous vessels, and in the same vessels at differ-
ent times - it was observed too that irritation
made on these vessels caused various and opposite
currents in them - and these phenomena were attrib-
uted to peculiar properties and functions of these small
vessels, quite different from those possessed by arteries of
a larger size. But these appearances all flow
from the innumerable insertions or connec-
tions that exist in the capillaries, for from such a
construction, any contraction or dilatation of these
small vessels produced by an obstruction of their
canals or by irritation from without, would
make the blood inifferently in any direction -
It was further remarked of these capillaries
that in certain cuticular diseases they were
so distended with blood as to cause a visible red

5. It was observed too that the blood some
times moved onward in these small
vessels, after the heart had ceased to beat.

18

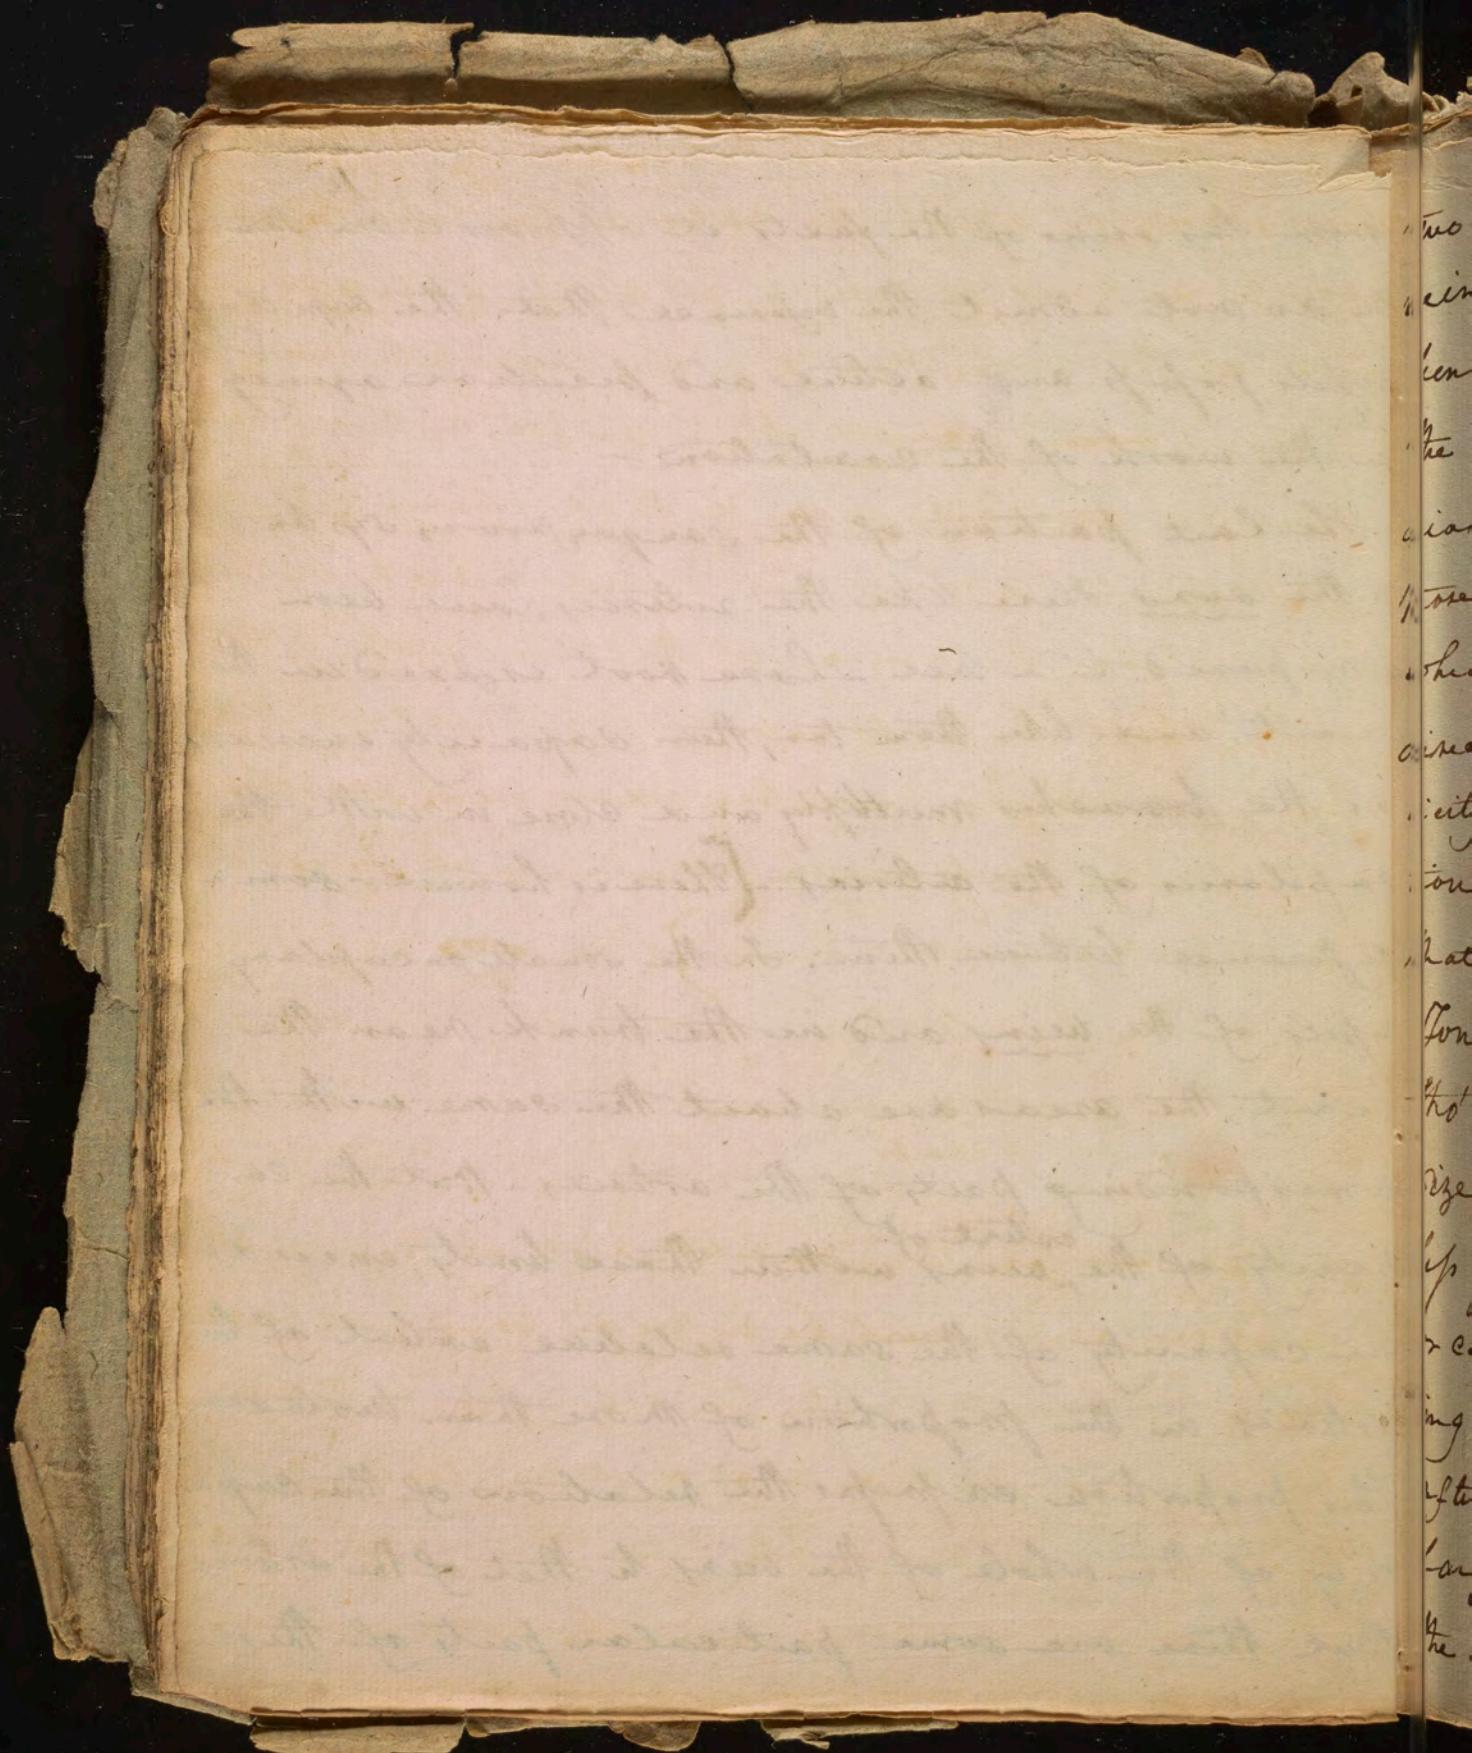

ref on the surface. and under the influence
of certain vapors they were seen to be con-
tracted into ^{VI}palp, and enlarged to suffusion.
These facts seemed to point out an active and
peculiar function in these vessels. - But from what
I said on the subject of the Tonicity or the per-
manently contracting and dilating power of the
larger arteries, you are prepared to understand
these appearances. The capillaries then do possess
the same tonicity as these, and the facts in ques-
tion proceed from the same function of the
large arteries continued to the smaller, and
perhaps it is exerted as frequently in one as in
the other. But the variations of the dimensions
of the larger tho' measurable, are not so often
or readily perceived; whereas the capillaries
of the skin exhibiting their contained blood
through their transparent coats, so sensibly and
quickly show by their color ~~when~~ the volume
of that blood is increased or diminished. -

18

From this view of the facts it appears to me that they do not admit the inference that the capillary vessels possess any active and peculiar agency in the work of the circulation.

The last portion of the sanguiferous system is the veins. Here like the arteries have been compared to a tree whose root is fixed in the heart. and like them too, their capacity increases as the branches multiply and close in with the capillaries of the arteries. [There is however some difference between them. In the small or capillary vessels of the veins and in the trunk near the heart, the areas are about the same with the corresponding parts of the arteries - But the capacity of the ^{extents of} veins within those limits, exceeds the capacity of the same relative extent of the arteries in the proportion of more than two to one. This proportion expresses the relations of the capacity of the whole of the veins to that of the arteries. But there are some particular parts of these

19

two systems, in which the ratio of the capacity of veins to arteries is much greater. Thus at the bend of the arm, there are five veins returning the blood ~~from~~ conveyed by a single artery whose diameter does not exceed that of any one of those veins - The veins are provided with valves which allow the progress of the blood in but one direction from the extremities - They have more elasticity than arteries, hence they allow greater distension and readily return to their usual size when that distension is removed. } They ~~also~~ possess a tonicity similar to that ascribed to the arteries tho' in the veins it produces a variation in the size of the tubes, ^{perhaps} frequently, and certainly w^{t.} less force. - That this tonicity exists in the small or capillary veins, must be inferred from their closing to blood equally with the arteries, a short time after they are divided - and its existence in the larger veins is palpable, in the variation of the size of these vessels, so frequently occurring in

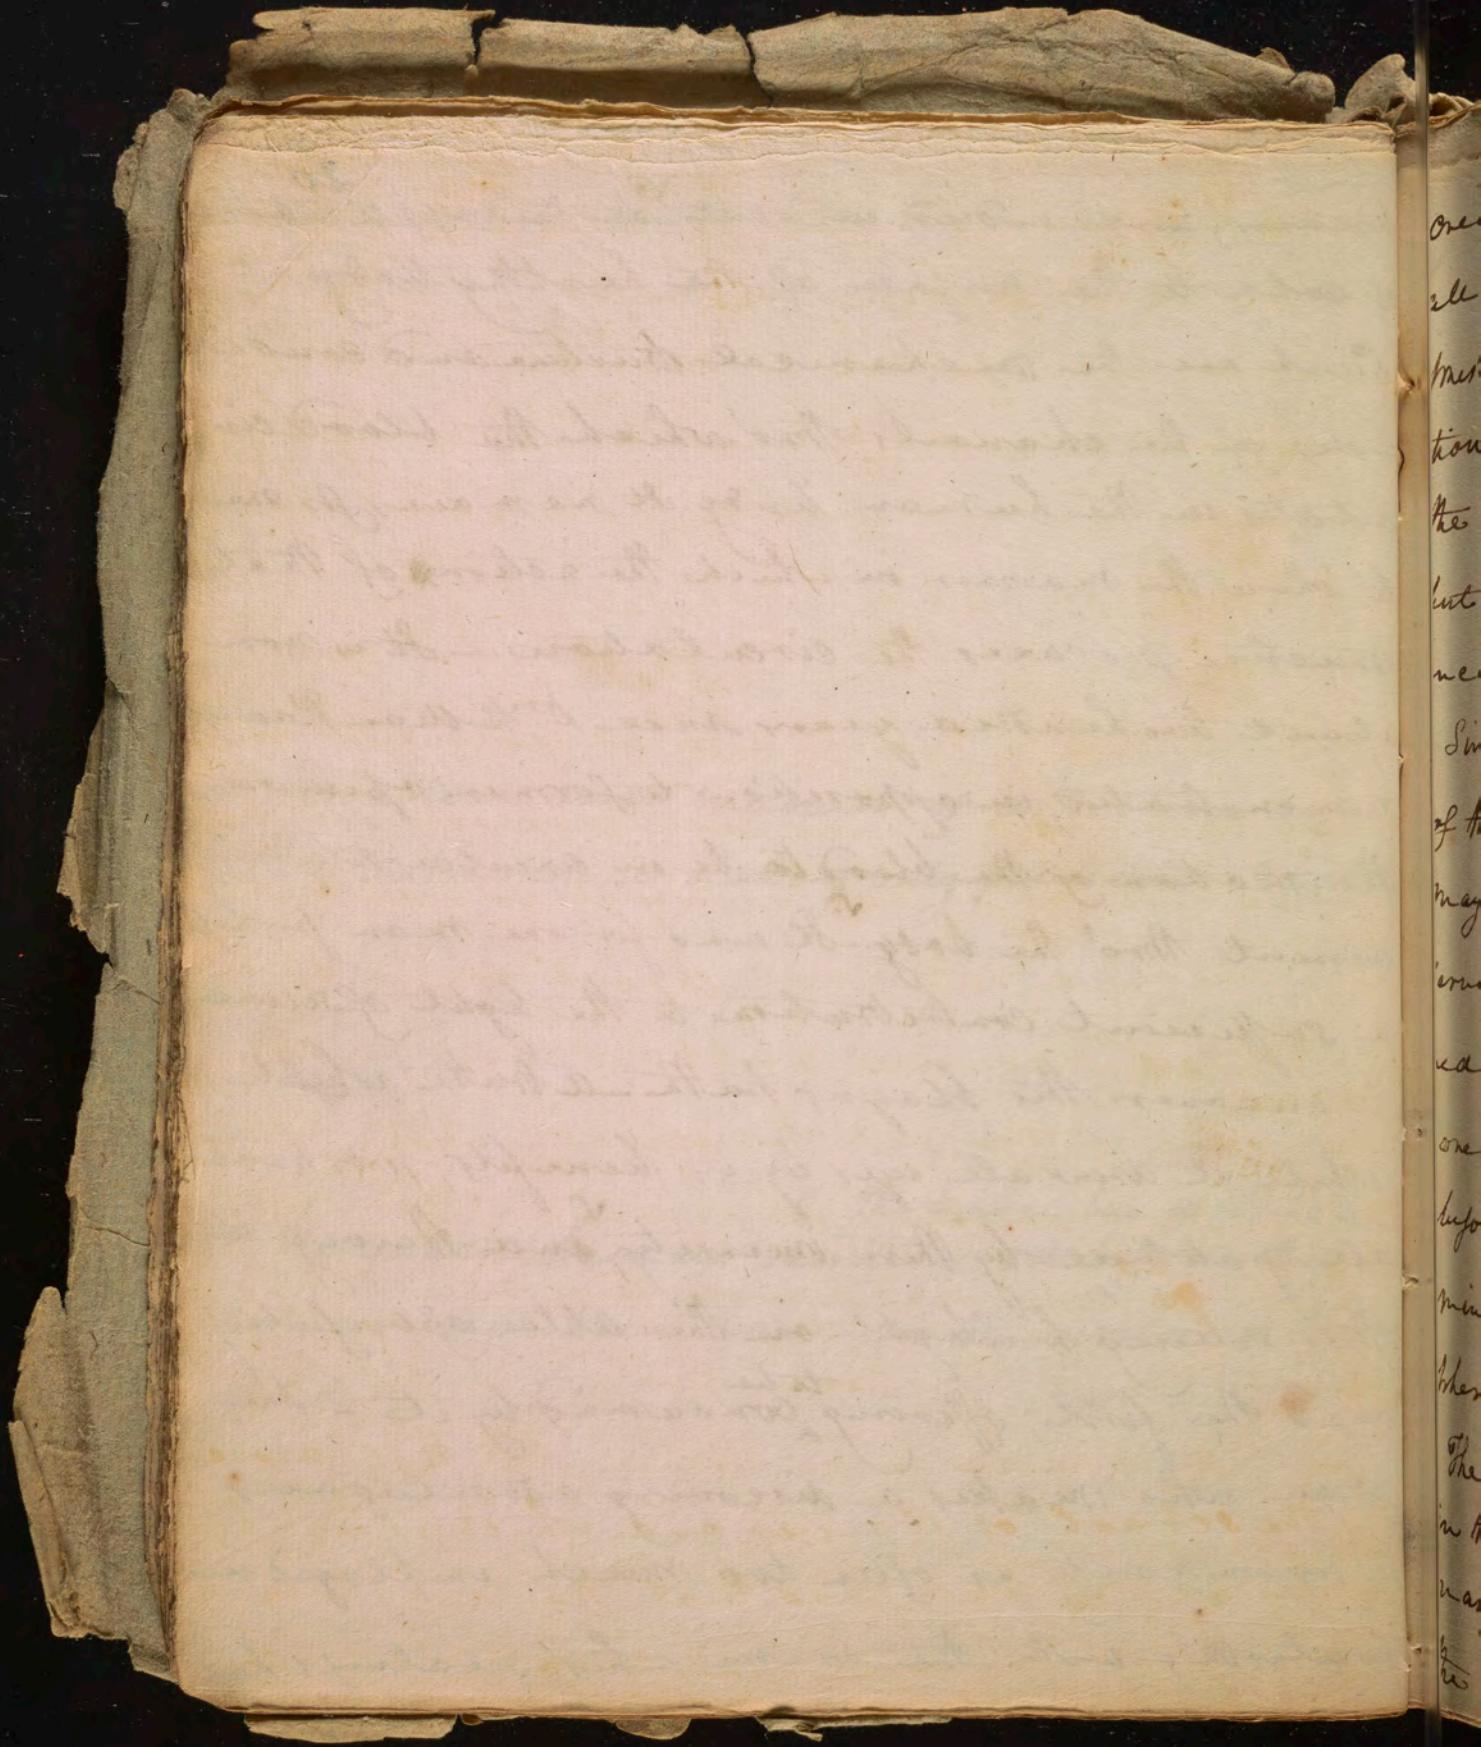

✓ from their contraction

✓ The detail and manner of its motion were
still unknown for Harvey only pointed out its path.

✓ The greatest human sacrifices ~~set before~~ the
world have been made for the service of man
kind -

20

diseases, and indeed evident ^{V.} on the application
of cold to the surface of the healthy body. —
Such are the mechanical structure and condi-
tions of the channels thro' which the blood cir-
culates in the human body. It remains, for me
to show the manner in which the action ^{V.} of that
structure produces the circulation. — It is now
about two hundred years since Dr. William Harvey
demonstrated, in opposition to former opinion,
the motion of the blood to be in circular returning
current ^{V.} thro' the body. — It was for one man perhaps
a sufficient contribution to the light of science
to uncover this blazing truth. — a truth which
while it drew all eyes by its benefit, prostrated
all gratitude by their intensity, and Harvey in
thus setting his light on the altar of usefulness
was the first offering ^{to be} consumed by it. — The
man who makes a discovery advantageous
to humanity is often too much employed in
contesting with the enemies his greatness has

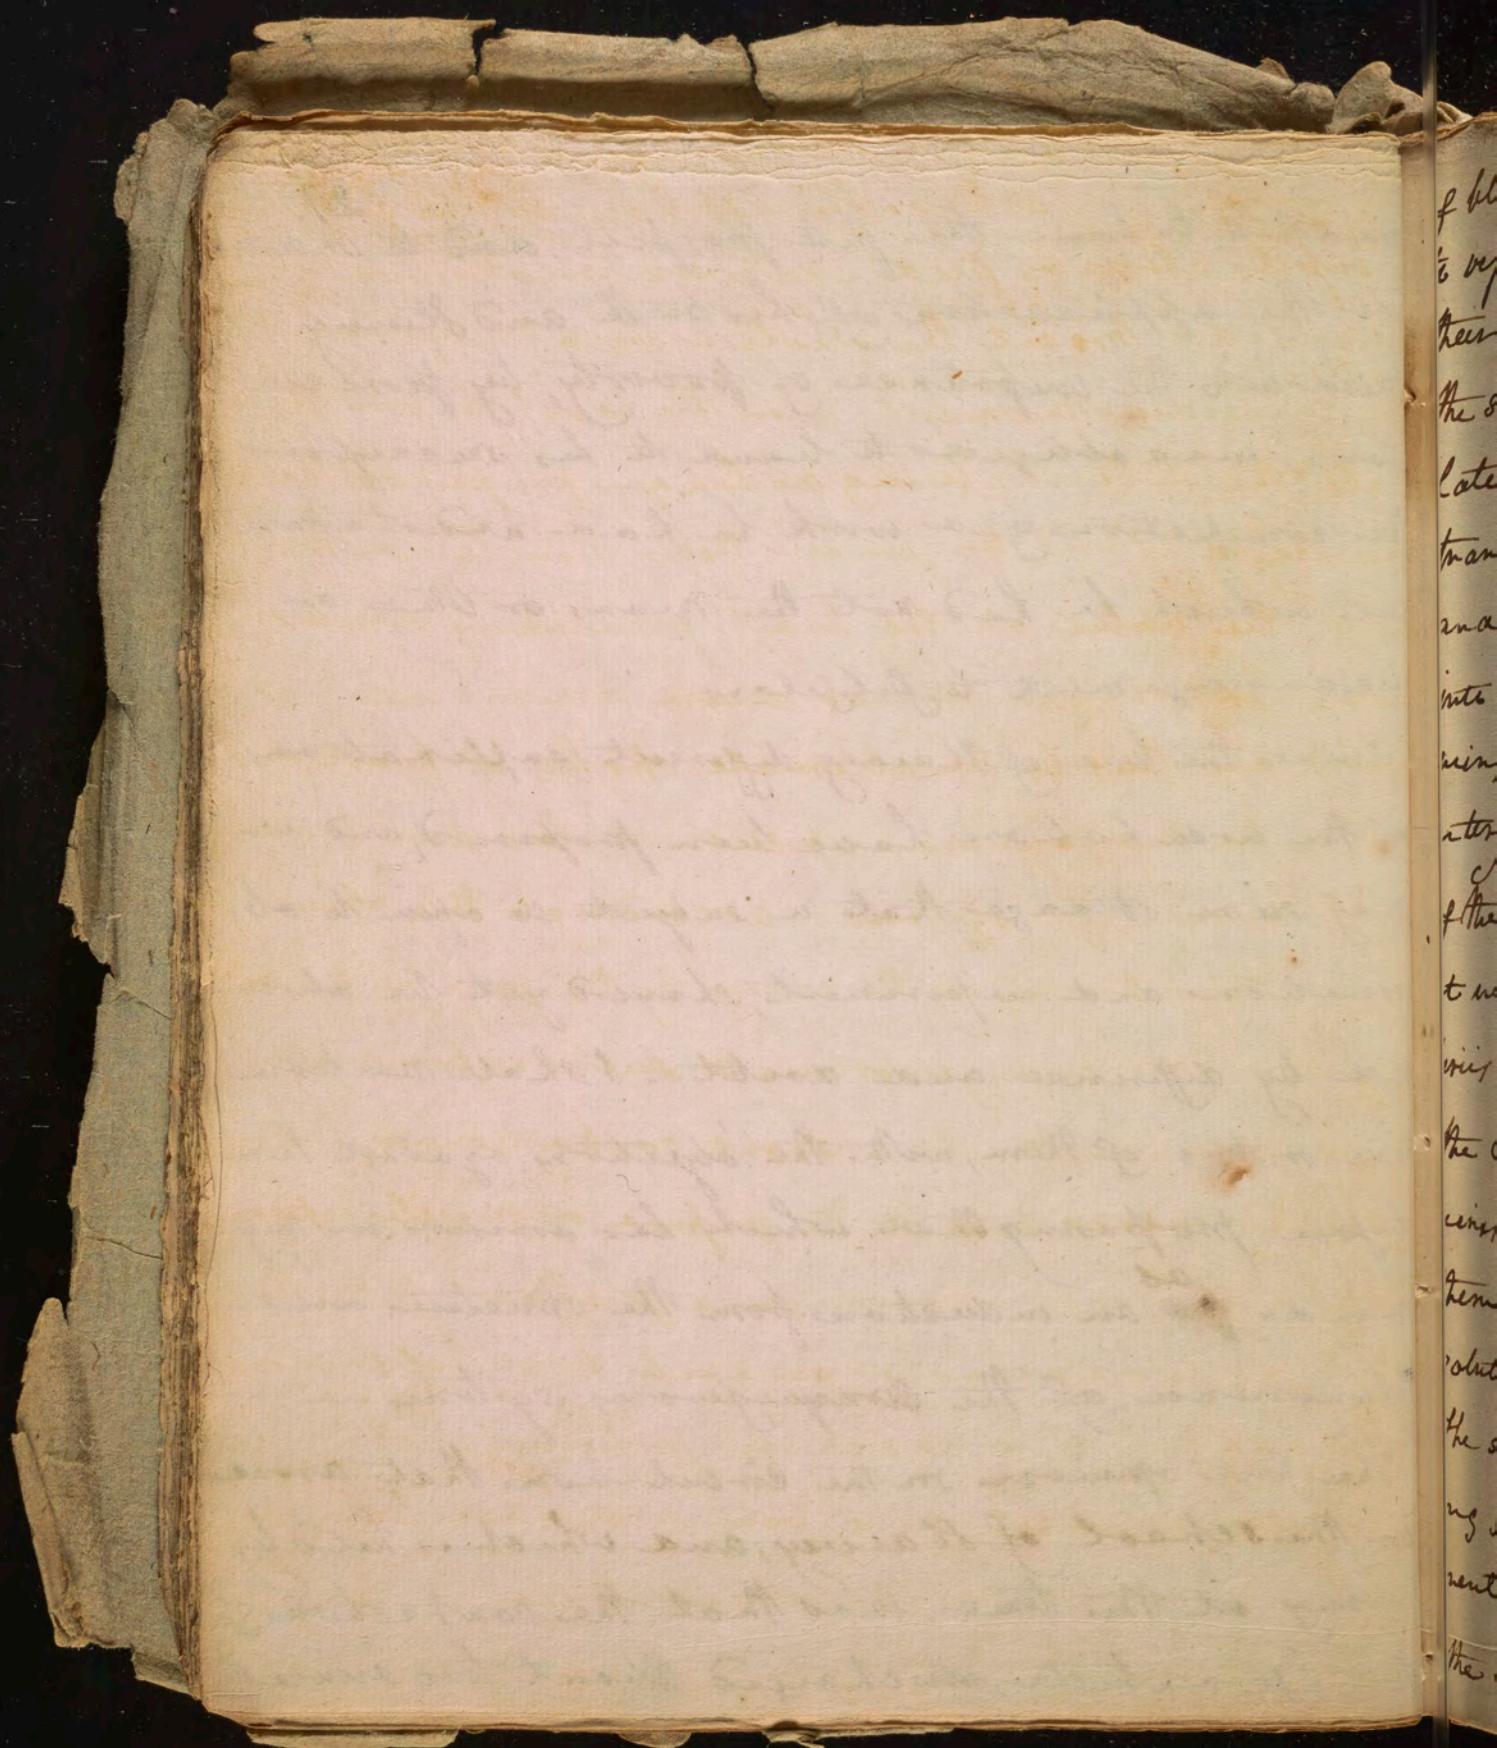

20

created to have the full prospect and to make
all the applications of his book. and Harvey
made into the importance of poverty, by perse-
cution - was obliged to leave to his successors
the completion of a work he had undertaken
but which he had not the means or time or
encouragement to fulfil -

Since the time of Harvey different explanations
of the circulation have been proposed, and it
may seem strange that a subject so open to ob-
servation and experiment, should yet be ob-
scured by difference and doubt. - I shall mention
one or two of them, with the objections against them
before proposing that which has arisen in my
mind ~~for~~ ^{as} an induction from the structure and
phenomena of the ~~vascular~~ ^{vascular} system -

The first opinion on the circulation that arose
in the school of Harvey, and which is held by
many at this time, was that the contraction of
the left ventricle, discharged about two ounces

22.

of blood into the artery. The addition of this quantity to vessels already filled, caused a dilatation of their sides thro' out the whole arterial system. In the succeeding moment when the heart began to dilate the arteries being no longer prepared by the entrance of blood, began in their turn to contract, and the valves at the heart preventing its return into that organ it was driven forward into the veins, and thus by the alternate stroke of heart and artery, the motion was effected in this first section of the circulating system. — According to this opinion it was contained in the veins, by the force of the air in the hinder, by an absorbing or suction power in the capillary veins, by a slight contraction of the veins themselves, and by the pressure of muscles upon them. — There was indeed some plausibility in this solution considered as an early trial of enquiry. The sensation of a shock on preparing an artery, being such as might arise from its sudden enlargement, the visible motion of superficial vessels, and the supposed necessity of an aid to the heart, to

overcome the resistance of the blood, were certainly facts that might have been without much reproach of reasoning to the false induction founded upon them. - This explanation however will be found inadequate, on a close observation and comparison of the phenomena of the circulation. It is assumed in this view that the heart alone cannot overcome the resistance of the vessels to the blood, and hence the necessity of the pulsations of the arteries. - Without rejecting this as mere hypothesis, it may be asked if there is any gain to the heart in thus adding to the resistance of the weight of the blood and its friction on the vessels, in adding $5 \frac{1}{2}$ oz to these, the further resistance of distending the most elastic coat of the vessels about their wider extended surface. - But admitting even this, and that the artery after being distended contracts upon its accumulated contents. it is plain the force with which it contracts must be less than the heart or it must be the same or it must be greater. - If it is less there is a positive loss, by the

V. is less during the

V. has the heart forced during the contraction
of the artery, when by supposition the power
of the artery exceeds that of the heart. -

heart expending a greater force in distending the arteries, than it receives in return in its contraction - If it be the same, there is no gain, and if the arteries contract with a greater power than the heart, how does it happen that on the division of an artery, the jet or momentum of blood is greater during the expansion of the artery, or the time of the heart's action, than during the contraction ~~of the artery~~ ^{of the heart} by opposition ~~to~~ ^{of} the force of the heart - But further if the arteries are distended by the blood from the heart, it must be because the blood does not pass out at the ~~other~~ ^{capillary} extremity or that it passes out slower than it is received, in either of which cases there would be a greater or less pulsation perceived in the veins - and yet the motion ⁱⁿ of the veins is of one uniform current. Again the arteries of the whole body if extended superficially would occupy a space greater than the surface of the skin. Now it must be evident that if the two streams of blood, thrown into them and which are supposed to cause their pulse, were spread on this

surface, it would not cover a fourth part of it
with a stratum of the heart measurable thereby,
Hence then could the two arteries when thrown into the
arteries and spread ~~throu~~²⁵gh them produce a sensi-
tive or ~~effe~~^{dilatation} ~~potation~~ in them. -

This last objection having been admitted as an
insuperable argument against the doctrine of
a general dilation and contraction of the ar-
teries, an other attempt was made to solve the
problem of the circulation by considering the
action of the artery as partial, some physiologists
then acknowledging that the two arteries projected
from the heart, was not sufficient to distend the
whole of the arterial system at once, to any ~~sensible~~
~~un~~ dimension - aparted that the quantity of two arteries
might produce the requisite enlargement ~~throu~~
~~un~~ a certain extent of the artery, suppose twelve inches
from the heart, this portion then contracting, pro-
pels part of its contents, into a second portion of the
artery of a certain extent, and thus by a succession
of these ~~un~~ pulsations of limited portions of the

stands in a logical point of view -

artery continued to the extremities of the capillaries,
the blood being obstructed by the valves at the heart
from returning was carried forward to the veins -
It was in short making these successive portions
of the artery, so many cylindrical hearts, only having
no valves between them. ~~and it is now of course
obtained, that the action of the heart is
to move each of these successively, so that they
may all complete the circuit of the artery
exactly in the time of one contraction of the heart.~~

In reviewing this rationale of the circulation I
need scarcely tell the young of you that it
is altogether an hypothesis, for what observation has
marked and indeed could mark the motions
on which it is grounded - It may perhaps be re-
garded as merely one of those schemes, so common
in science, for the development of subjects on
which knowledge is both desirable and de-
sirous. - ~~The first consideration is that
the circulation is not yet fully understood~~

5. It is assumed in this theory that whilst the ventricle is contracting the first portion of the aorta is dilating to receive the injected blood. Whilst the ventricle is in the pause of its dilatation this first portion is contracting and the second portion of the aorta is dilating to receive the blood prepared by the first portion, so that

opposite minima, there is no agreesance between
 they are the first, for if the dilatation of the
 successive pulsations of the arteries, from the height
 to the extremities be all made in that single
 part of time, in which the left ventricle contracts
 it would be impossible for the exsanguineous to dis-
 tinguish any variety in the time of their successive
 pulsations. The pulse would therefore appear to
 proceed at a uniform dilatation & abstraction
 (or exsanguination) as the basis of the pulse
^{mark}) But even as an hypothesis it will be
 easy to show that the operation of the proposed
 scheme would produce effects very different from
 the real phenomena of the circulation. —

^{v.}
 If a cylinder like whose sides are conical
 be filled with a fluid, and an equal quantity
 of fluid be poured into one end, at the same
 appearance instead of a equal quantity will flow
 from the other extremity which will be the longer
 of the tubes. — So since the arteries quantity can
 not enter but by the discharge of an equal bulk

the ventricle and the second portion are both in dilatation at the same time, whilst the first portion and the third are contracting at the same time - and as this alternate action is continued to the end of the arteries, the progression of the odd numbers of these sections will be in a state of dilatation, at the time the progression of the even numbers are in a state of contraction, any two ~~of~~ contiguous portions will therefore in their actions, resemble the alternate action of the auricle and ventricle of the heart. - Since therefore there is as much of the whole extent of vessels in the state of contraction as the reverse, it is impossible there could be that universal synchronous stroke that is felt in the arteries. - But further there is a fact on the subject of this synchronous stroke that points out more precisely the utter impossibility of such a succession of action in the artery as the theory supposes. - It has been shewn by the detail of this theory

to explain the reason of the varied quantity in the
case of the motion of that discharged, an account
may be given why the velocity of the first
part by ~~itself~~ increased or decreased, con-
sideration, it follows that the velocity of the
two quantities must be equal, and the same will
be true of all the intermediate quantities of fluid
so if it were otherwise, there would be a compres-
sion of this intermediate quantities, or a dilation of the
cylinder, which by the construction of the propulsive
or propulsive - the velocity and space incre-
ased by the whole fluid will be increased by the
velocity and space of the admitted fluid quantity.
This motion of fluids as it is called a part to the mo-
tion of solids, indicates the motion of the solid col-
umn of fluid, he said as in them there is no ac-
tual motion of the relative portion of fluid, but
an absolute motion of the whole. But the case
is different with fluids flowing thro' elastic tubes,
for here if the resistance to the discharge be greater
than the resistance of the elasticity of the tubes
these will be altered on the admission of any fluid

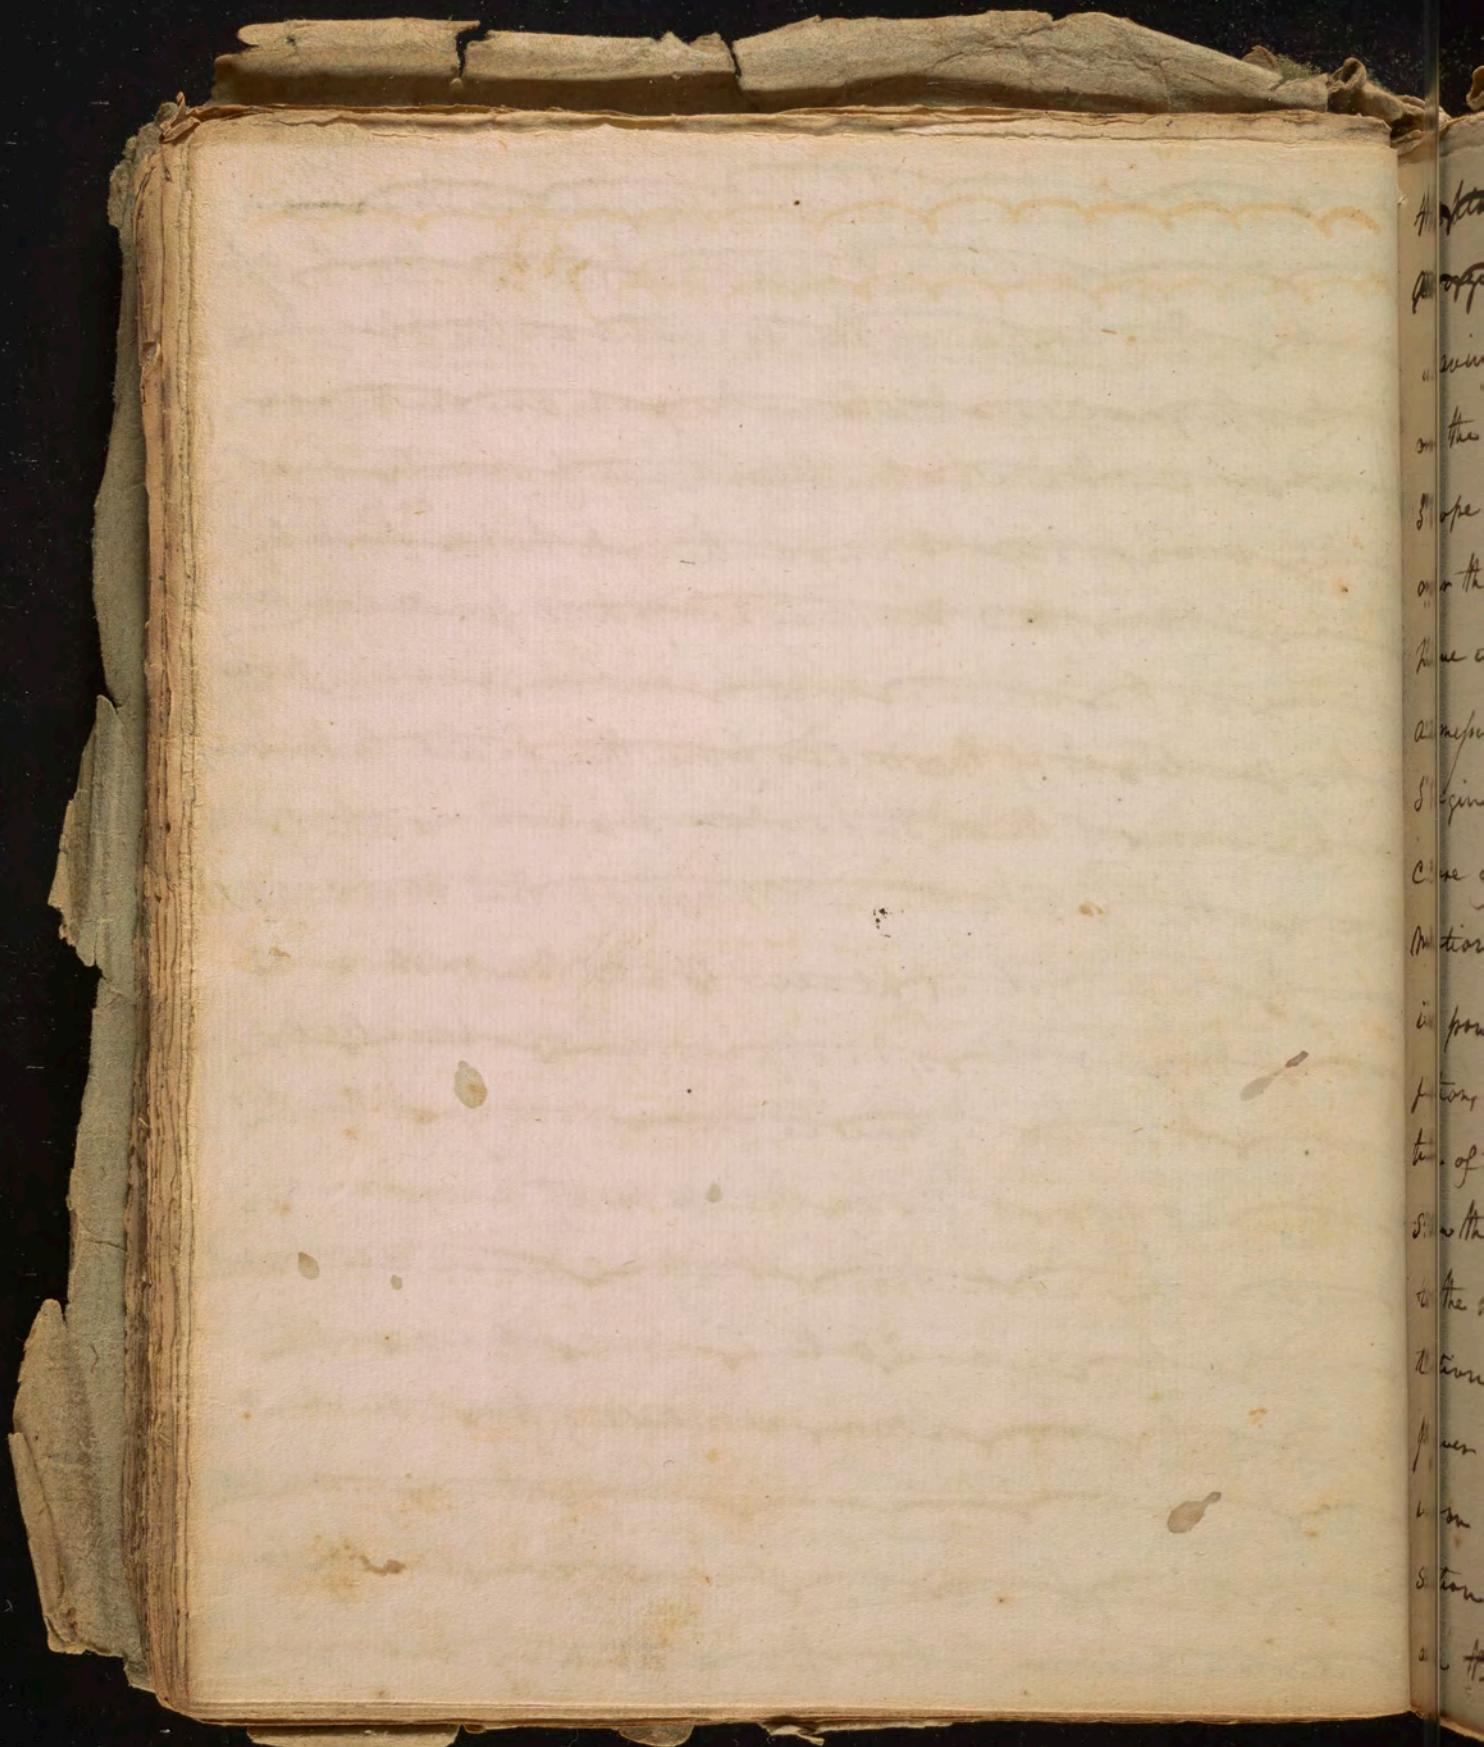

that when any one of these limited portions of the artery is in a state of contraction and propelling its contained blood, the next portion in advance is at the same time dilating to receive it, as they then exactly resemble both in the mode of their motion and their effect the auricle and ventricle of the heart, we may take the terms of auricle and ventricle as convertible with those of any two portions of the artery, so that the whole of the arterial course will represent an alternate series of auricles and ventricles. Recollect however that I make this substitution of terms and this analogy only to afford an easier comprehension of the argument. — Now suppose ten auricles and ten ventricles thus alternately continuing with each other. — It is plain that the blood cast on by the contraction of the first ventricle cannot reach the tenth, till it has successively undergone the contractions of the eight intermediate ventricles, that is the blood can not reach the tenth ventricle, until the time occupied by eight

quantity of fluid, the space is given equal to the
bulk of that species, and no discharge will take
place and thus the motion will not be of the solid
column but of the particles composing that column
whose relative position will be changed by lateral
and other motions to fill up the yielding ^{space} of the
of the tubes. - Now to apply this to the hypothesis
before us. When the heart projects its two surces of blood
into the first portion of the aorta which we have
seen to be twice in bulk, the sides of the vessel are distended
and by a space capable of containing this additional
quantity, and now is discharged from it, and more
blood from the heart, upon the extraction of this
portion of the vessel a quantity equal to that of the adi-
ditional bulk received is discharged from the end re-
mote from the heart, into the second portion or sec-
tion of the aorta, this second section performs the
same action and discharges the blood into the veins
and thus it is carried thro a the successive
sections which continually diminishing in bulk
as they approach the heart. For as it is the
quantity of blood thrown into one of these sections

successive contractions will have elapsed -
and the same will happen if there should
be a pause of the first ventricle, and no blood
should be cast out. - That pause or that ~~dis~~
giving of blood will not be felt by the
left ventricle till the time of all the interme-
diate ones has elapsed. - & instead of the left
the right be taken it is evident that the time
in which the pause will be perceived in it will
be less - so that it is impossible that the pause
can be felt at the same time in any two differ-
ent ventricles. - Now in the circulation of the
blood the heart occasionally suffers such a
pause as we have been supposing, on such
occasions I have proved with the aid of an op-
erating, as any of you may prove by like obser-
vation, that the pause is felt in all instances
of the arteries, in the Carotid, at the ankle and
at the wrist, at the same instant of time -
a theory therefore that contradicts a manifest
phenomenon of the circulation cannot be true

30.

that it increases its length, it follows that in
the expulsions, where the quantity is the least, especially,
the length of the section will also be
less of magnitude, which will give an immense
number in the whole distance from the heart
to the veins. But I am willing to take ^{only} twenty
of the sections, and they may be prouid for more
numerous, as the elements of a calculation now
as the motion of the blood from the heart to the veins
and the cause of these ²⁰ successive sections is all effec-
ted in the time of the discharge of the two gaves
from the heart, it is plain that the motion of
one of these sections is effected in one twentieth
part of that time, that is, the velocity of the dis-
charge of blood from the heart of anyone of
these sections, with the velocity of blood discharge
from the heart a 20th part. But who does not
see that the motion arising from such a
velocity of the blood must be constantly out of
time to the system, where it is so constantly found
that it stands on to the ordinary methods of

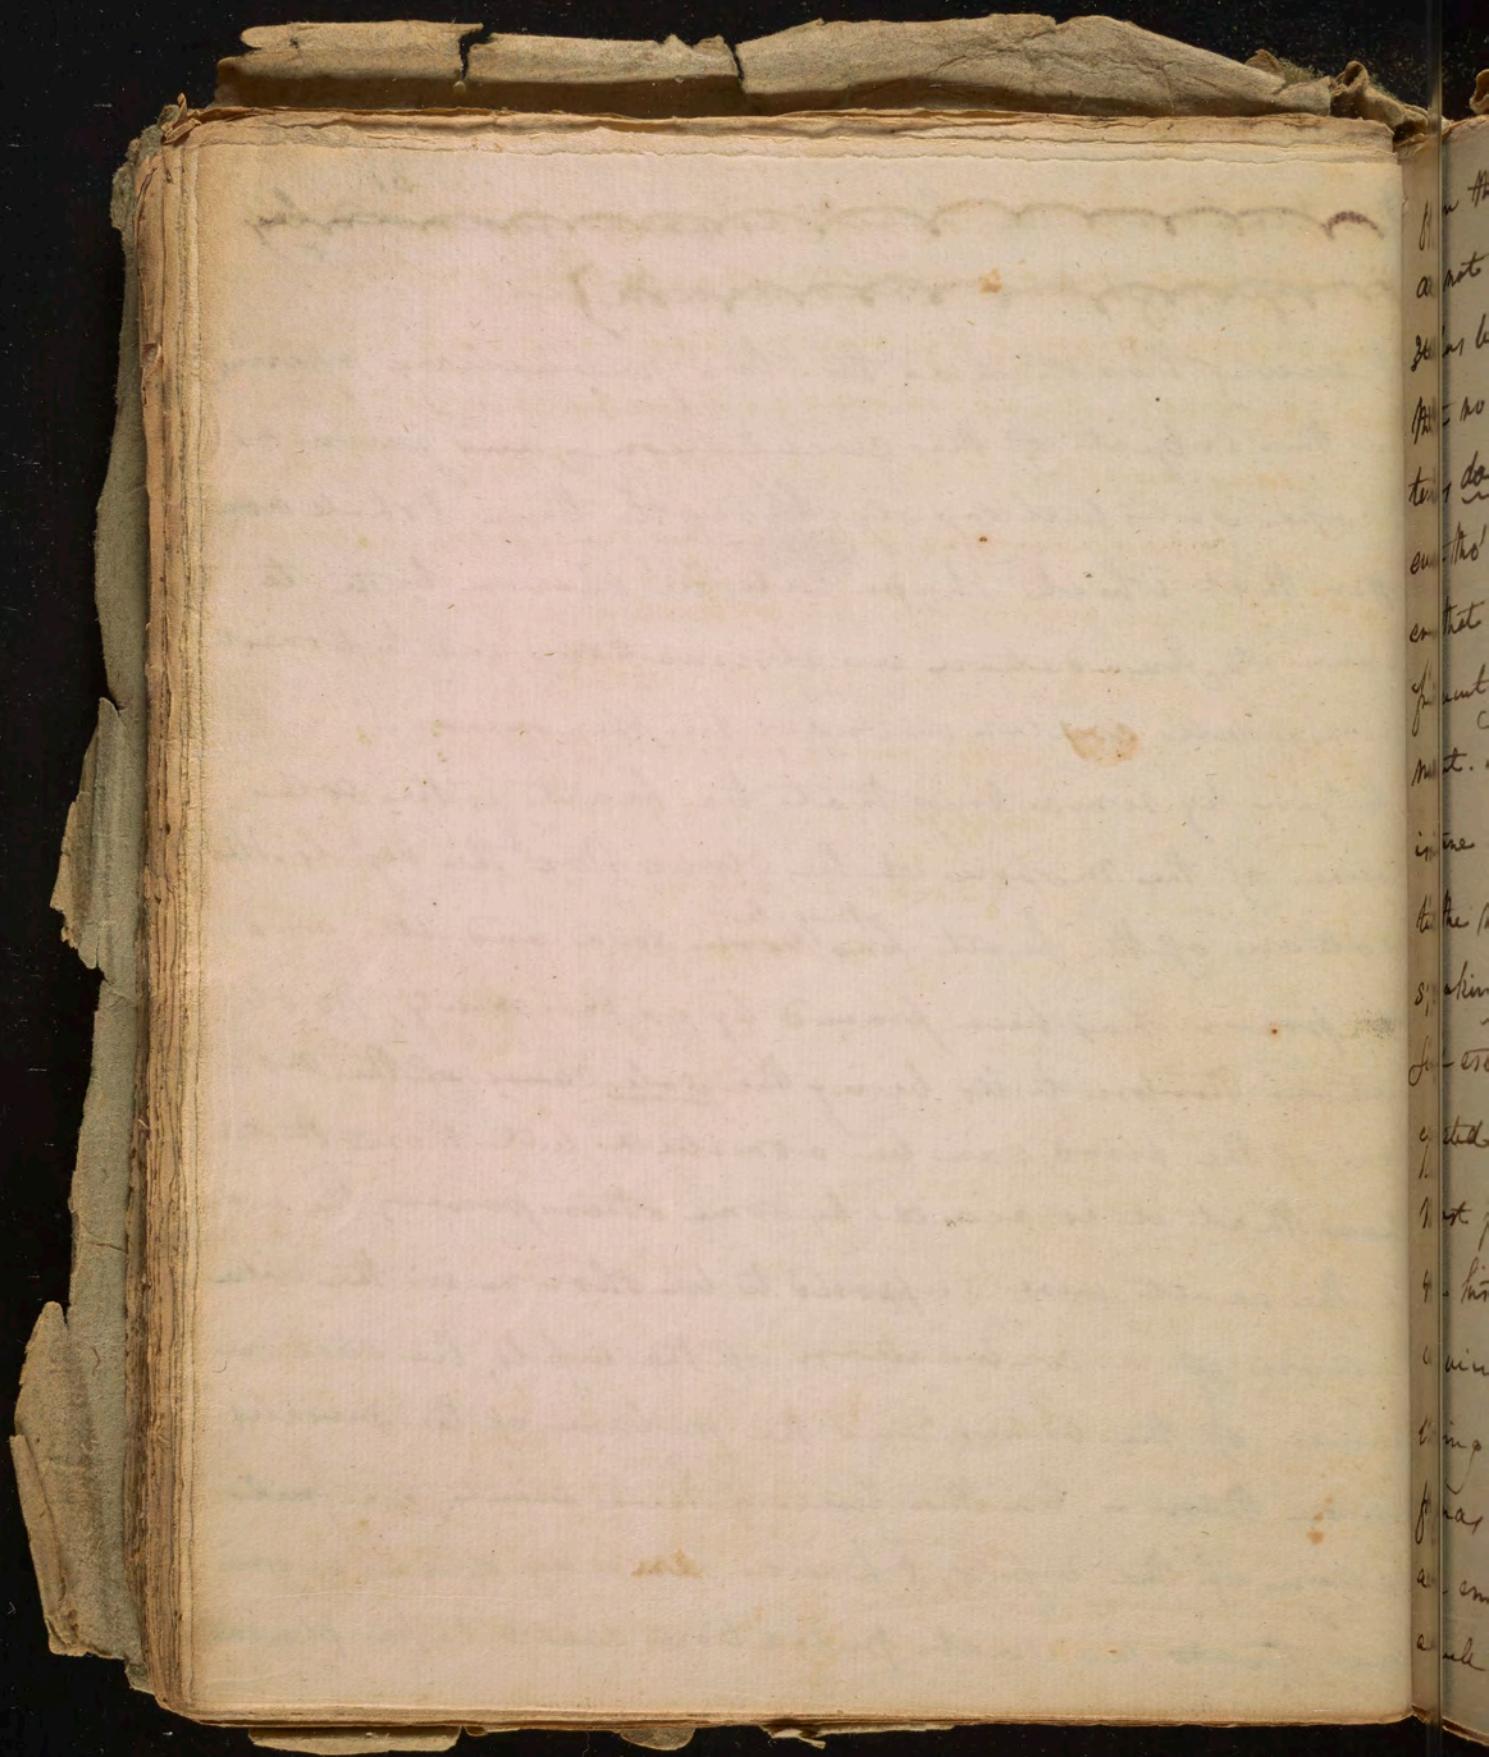

31

~~Not to do the heart to move forward by
propagation of motion~~) -

Having thus stated the two prevailing opinions on the subject of the circulation, and given as I hope satisfactory objections to them, I shall now offer that which I hope will be shown both to have its foundation in observation, and to furnish admissible explanations of the phenomena. -

I begin by remarking that the heart is the sole cause of the motion of the blood thro' the vessels. The motion of the heart ~~has been~~ ^{may be} seen and felt, and its power has been proved by experiment, no objection, therefore to its being the ~~sole~~ cause of the motion of the blood, can be admitted, but those that show that it is aided by some other power, The aids to the heart were supposed to be shown in the dilation and contraction of the vessels, the suction power of the veins, and the pressure of the muscles upon them - On the first of these points, the pulsation of the vessels, I have already shown a principle that no such pulsation could take place

from the operation of its supposed causes, But I
do not wish my argument should rest on this alone.
It has been proved by observation and experiment
that no such dilatation and contraction of the ar-
teries ~~does~~ exist. — It has been admitted by Haller
even tho' he ascribes the pulse to the dilatation of the art-
ery, that the inspiration of the ~~arteries~~ ^{veins} of living animals
frequently exhibits no sign of their attenuate move-
ment. Bischat afterwards denied altogether the ex-
istence of this dilatation and ascribed the pulse
to the motion of the whole artery, or what he calls in
speaking of the arteries, their locomotion. — But the
full establishment of this opinion has lately been
effected by Doctor Parry of Bath by ^{an animal} a series of the
most precise experiments. — Doctor Parry has given
the history of 27. different experiments made with
a view to discover the functions of arteries in
living animals. In these assisted by his medical
friends he exposed different vessels, and tho' they
all employ ^{used} the most delicate observation
as well as ~~with~~ some modes of mechanical

Analyses in nature are not wanting, to warn us of the problematical nature of this assumption - which seems to be grounded only on the idea of the necessity of and universality of attraction, - The apparent repulsion or at least the want of attraction between water and the leaves of some aquatic plants, shows us one of these analogies. May the polished cast of theボタ ^{ボタ} be another of these surfaces? -

measurement, they were unable to detect the least dilatation or contraction of the artery. - There was no exception here from the exposure of the vessels, as the pulse was felt on pressing the vessel as sensibly as before it was laid bare. -

We see then no possible foundation for the opinion that the arteries afford any aid to the heart in carrying on the circulation. The idea of aid being derived from capillary attraction in the veins, or as it is call'd thin suction power, is equally unsatisfactory. In the first place as it is said to take place in vessels too minute to be the subject of observation or experiment, the existence of this capillary attraction between the internal coats of veins and the blood is entirely an [✓] assumption. - But allowing its existence it is easy to see it must be an obstruction to the advancement of the blood, but it cannot without an absurdity be supposed as a cause of its progr^{ss}. With regard to any aid from the muscles ^{by the} of their pressure on the veins, during their action, I would only observe, that this cause if it were

¶ Thus if a cylindrical tube whose sides are unyielding be filled with an incompressible fluid, and an additional quantity be pressed into one end, at the same apparent in-

34
spectual could be so only occasionally, and
therefore discours no conversation, in an enquiry
after the continual causes of the circulation.

As ^{then} no cause can be shown to afford aid to the
heat, it remains for this organ alone to carry on
the circulation. The sufficiency of its power I hope to
make manifest in

As the action of the heart is exerted in producing
motion in a fluid, it will be necessary for the un-
derstanding of what I deliver, to explain to you ~~the~~ ^{a law}
of moving fluids. — Fluids, from their consisting
of particles, easily moveable among one another, and
possessing little mutual cohesion are capable of two
kinds of motion, the one a motion of their whole mass
common with solid bodies, the other a vibration
or undulation of the particles, themselves, communica-
ted successively from one to the other thro' out the
whole mass. ~~This is in solid bodies~~ ^{If in} and
from a fluid in at the upper end it will quickly
pass thro' and be discharged at the other, here then
is a motion and sensible velocity of the whole mass.

start an equal quantity will flow from
the other extremity. For since the admitted
quantity cannot enter, but by the space
afforded by the discharge of an equal bulk
it is plain the admitted quantity, is the
cause of the motion of that discharged, and as
no reason can be shown why the velocity
of the first should be either increased or de-
minished during its communication, it follows
that the velocities of the two quantities must be
equal, and the same will be true of all the
intermediate quantities, for if it were other-
wise there would be a compression of the
fluid ~~bodies~~ or a dilatation of the cylinder, which
by the conditions of the proposition is impossible. ~~of sea~~
This motion as it is analogous to the motion
of solid bodies, is called the motion of the
solid or continuous column of fluid -

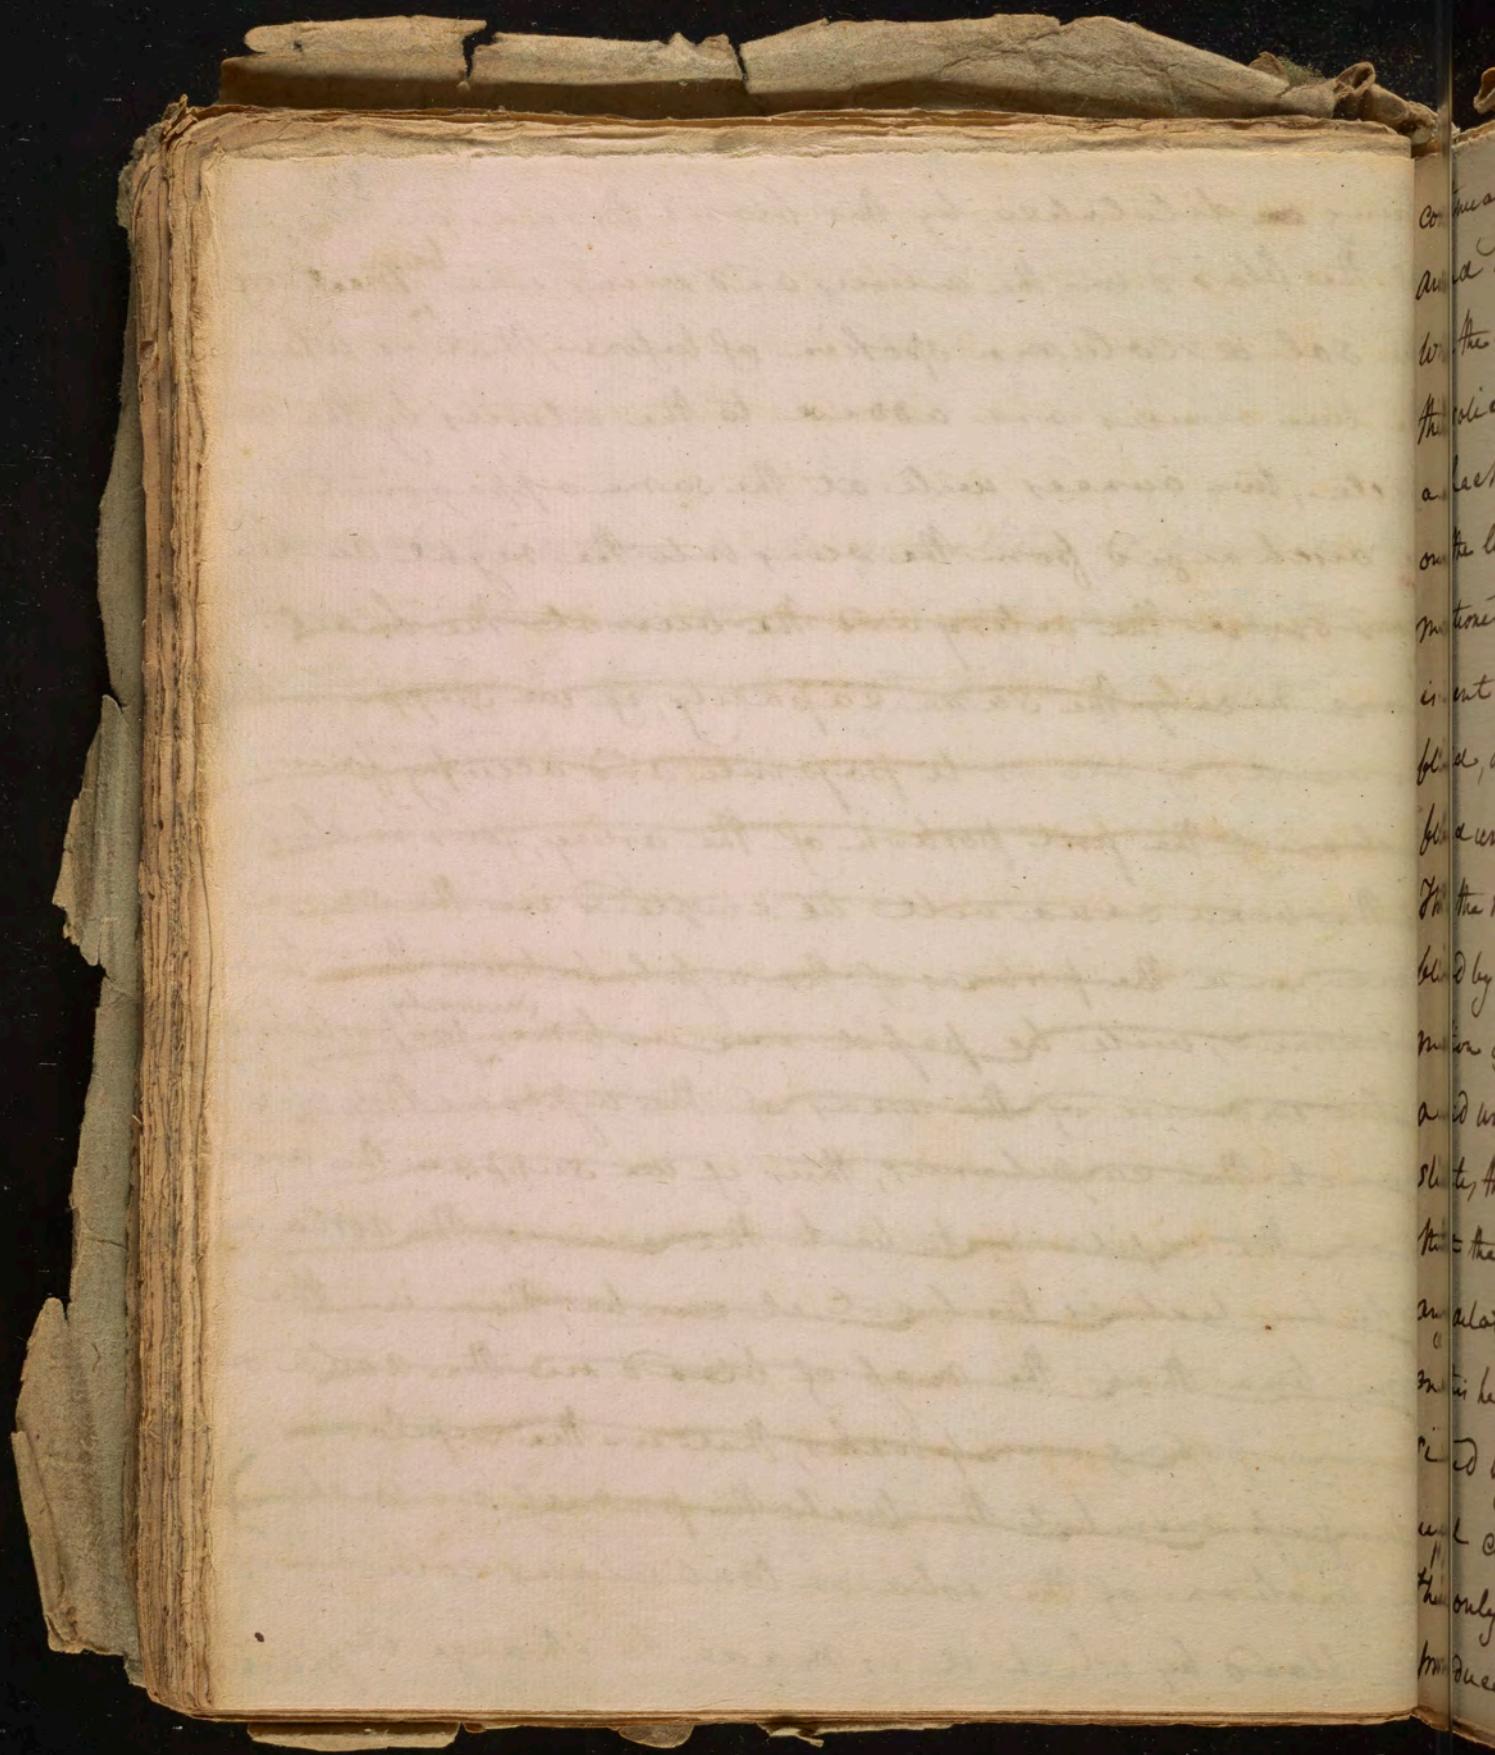

But if the same tube be filled, and each end
be covered with a piece of leather, a blow or shock given
to one of these pieces of leather, will be felt in the same
instant, by the finger applied to the other.³⁵
Now this exhibits, and illustrates the vibration or undula-
tion of the particles of the fluid, for in reality each par-
ticle of the fluid does go forward and return thro' an
infinitely small space, and this vibration being con-
tinued on to the end of the tube does there, by the
forward motion it gives to the last stratum of particles,
impress the finger with the pulse that is felt. - tho'
it is true that fluids when acted on press in all directions,
yet in this case if the tube be rigid or undilatable
there will be no lateral vibration, for since all vi-
bration requires space, and since no lateral space is
offered by the permanent diameter of the tube, it
follows that the longitudinal vibration or undulation
is the only one that can take place or be felt in the
tube. - Now tho' these vibrations are positively more
nearly thro' space, yet the spaces are so small or the
times so quick, that they produce no visible velocity
in the particles of the fluid that are ^{in the middle of the tube or that are} surrounded by

v. or let the latter be taken from the extre-
mity, the party at the end of the tube ha-
ving nothing that they may impast their mo-
tion to.

other particles, but ^{let} the advanced particle be at any place removed, ~~the remaining particles having then before them to impede their motion~~, will now be carried off from the mass with a visible velocity. The same would take place if the sides of the rigid tube which allowed no lateral vibration were to be opened, for space being thus afforded for a lateral vibration the particles at the aperture w^d be carried off with a visible velocity. — A familiar illustration of this may be given you by the action of a series of ivory balls. — If any number of these be suspended in contact in a line, and the first be struck the last will in the same apparent moment fly off with a visible velocity, whilst all the intermediate ones will remain apparently at rest, tho' it is certain they have posse'sd all the motion the last exhibits, but for so short a time as not to allow a visible velocity. — To apply these remarks to the circulation. Let us suppose the heart and blood vessels filled and that the left ventricle contracts, two ounces of blood will thus be driven into the aorta, the arteries being unyielding tubes, at least ^{not} ~~them~~

• and all the intermediate quantities of fluid will
move forward with a velocity inversely pro-
portional to the capacity of the vessels thro'
which it flows. —

being ~~more~~ dilated by this blood thrown in, the mo-³⁷
~~of the blood in the artery and veins will be that of~~
~~the solid column spoken of before, that is when~~
~~the two arteries are added to the arteries by the ven-~~
~~tricle, two aures will at the same apparent time~~
~~be discharged from the veins into the right auricle~~
~~now since the artery and the vein at the heart~~
~~have nearly the same capacity, if we suppose the~~
~~two aures of blood to pass into and occupy four~~
~~inches of the first portion of the artery, four inches~~
~~of the vein will be emptied in the same~~
~~time, and the portion of the aule, between the two~~
~~extremes, will be passed ^{inversely} in time, proportioned~~
~~to the measure of the area of the aule as they ap-~~
~~proach the capillaries, thus if we suppose the area~~
~~of all the capillaries to be to the size of the aule as~~
~~50 to 1 which is the least it can be, then in the~~
~~same time that the mass of blood in the aule or~~
~~veins is passing over 4 inches, that in the capillaries~~
~~will pass over but the twelve th part of one inch }~~
This motion of the solid or continuous column of
the blood by which it is made to change its place

continually in the vessels, is not the only effect produced upon the mass of blood by the heart, when the ventricle contracts forcibly on its contained blood the solid & solid parts of the cavity of the ventricle impinge a shock to the blood, which like the blow impressed on the leather in the instance of the tube above mentioned, causes a vibration or undulation that is sent out instantaneously to all parts of the fluid, diminishing however as is the case with all fluid undulations, in proportion to its extent. -- Thus the heart produces two manifest effects on the blood by its contraction, first a comparatively slow motion of the whole mass, and ^{secondly} an immeasurably rapid undulation. -- It is the last of these that constitutes the Arterial Pulse, I have already proved to you that the Throb or pulse of the arteries is not produced by any dilatation of the sides of the vessel, it only remains on this head to enquire if the Pulse may not be occasioned by the progress of the mass of blood along the vessel contradistinguished from the rapid undulation. The only manner in which the mass of blood could produce the sensation of a Throb or pulse would be

by flowing by jets or by an alternately increased
and retarded velocity, thro' the upl. But I shall
prove to you presently that the upl. of blood does
not flow in this manner, but in nearly as uni-
form current as it does in the veins - I will only
observe here that if the upl. of blood moved by jets in
the arteries, the same species of motion would be seen
or felt in the veins, for the blood in the arteries and
veins being one continuous column, and that two mo-
ving in the same circle, the kind of motion in one must
also be found in the other. without contrary reason
can be shown. Now this contrary reason is signified
to be shown in the increasing area of the arteries as
they approach the veins - for it is said the blood flow-
ing rapidly in the large upl., it produces there a blow
or throb which is felt as the pulse, but in the smaller
arteries the velocity is so much diminished as to prevent
the blood producing any sensible impulsion - This idea
is opposed by the phenomena of anæstomosis, for here
there is an increase of the area of the upl. by the dis-
tension, and consequently a reduction of the velocity
of the blood, and yet we know that the throb or
pulse, so far from being obliterated or lessened

to again, if it is the velocity of the blood that
causes the sensation of the pulse, how does it
happen, that when an artery is completely ob-
structed by a ligature, etc. there is a pulsation
and an increased one too, just behind the lig-
ature, where by the very condition of the parts, there
can be no velocity of the blood. -

in the sack of an aneurism, is generally much ⁴⁰ increased in its force beyond the pulse of the smaller artery leading into it - This fact is entirely consistent with the principle of the undulation & have cause done for if the pulse be produced by the rapid flight of the undulations from the side of the ventricle to the capillaries, or perhaps beyond them where it goes away, then I say it will pass with equal velocity whether the space of vessels thro' which it moves be contracted or enlarged - and in some enlarged parts of the sack of an aneurism, the undulation spreading in all directions thro' its cavity, will give from the greater bulk of fluid set in motion, a stronger impulsive on its walls being press'd - But further that it is not the velocity merely of the mass of blood passing under the finger that creates the pulse that is felt is evident from this, when it beats ^{from} ~~130~~ to 60 in a minute it is certain the velocity is about its greatest, and yet every practitioner knows that these rapid pulses are seldom strong. The strongest are generally when the pulse is from 50. to 90 when the blood is at its last velocity, ^{and} for it is in

These cases, that the pulse is often felt as if it were the
shock of a solid body contained in the vessels, for you
can readily understand that the whole mass of the blood
may move slowly from obstruction somewhere existing, and
yet at the same time that the heart may make a stron-
ger effort on its contained blood in consequence of this
obstruction - Now it is this strong effort or jerk of the heart
on the blood, that sends out the undulation that con-
stitutes the pulse even thro' the whole mass, move very little
may so widely may there two motions, in the arteries of the
mass of the blood, and the rapid undulation sent out, be
distinguished from each other, that I hope at some fu-
ture period to show you when beating of the diseased
pulse, that in some of those affections of the heart and
its valves where the pulse has its greatest fulness and
longevity and resistance, the whole mass of the blood
is propell'd with a mere creeping progress, if indeed
it be not on some occasions to be brought for a few
moments, altogether to a pause - I aptly above
that the blood moves in nearly as uniform a current
in the arteries, as in the veins - I have anticipated
your surprise, if not your immediate negative, on an

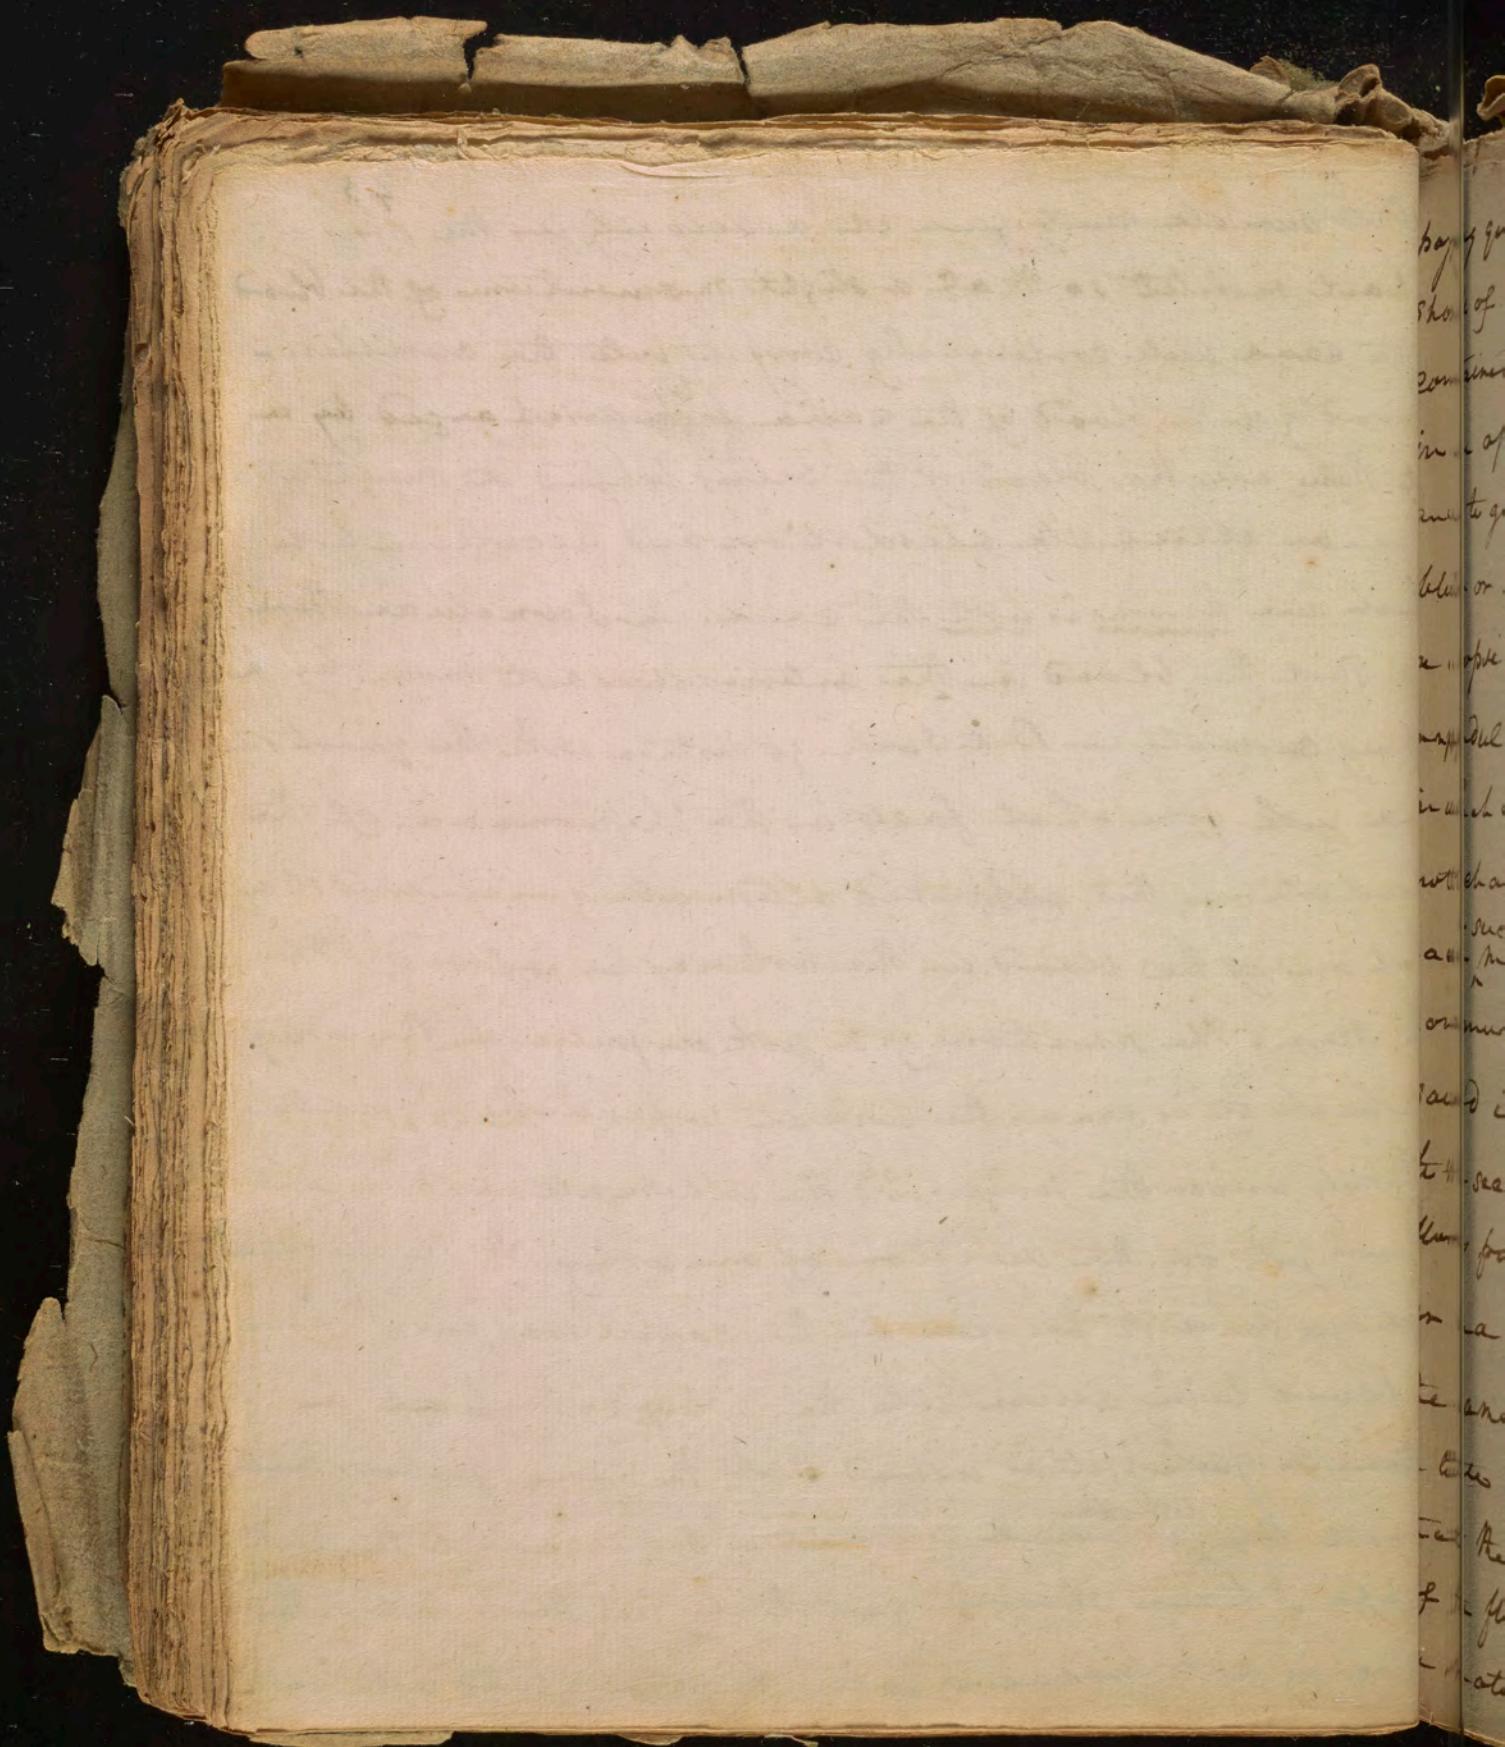

43

opinion so directly opposed to a doctrine universally re-
cived and which as far as I can learn has never
till this moment been even questioned. — ⁴² I have above
that ^{an argument} ~~now~~ given ^{under a} ~~two~~ ^{where} different aspect, ~~I say the~~ ^{such as} ~~again~~ that
in a fluid of one continued line or column ~~as in the~~ ~~such as~~
~~the~~ the blood in the arteries and veins, and where the mo-
tion of the second half of that column is derived ~~altogether~~
~~from~~ from the motion of the first. — I say it is at least incon-
ceivable that the motions should not resemble each
other in kind. — If a certain quantity is added at one end
an equal portion must pass off at the other: and if this
quantity be added to the first portions of the aorta by a
jet, it must fly off from the cava at the other end in a
jet. — But it does not fly off from the cava into the
right side of the heart in a jet, as may be ~~seen~~ by two
remarks. — First from these being no valve between the
cava and the auricle, the cava having filled the auricle
continues still to propel its blood into the auricle, whilst
this last is propelling its contents into the now dilating
ventricle. — For tho' the auricle does press strongly on its
blood, yet the vacuum of the ventricle soliciting and
assisting its easy flow in that direction, the pressure

43

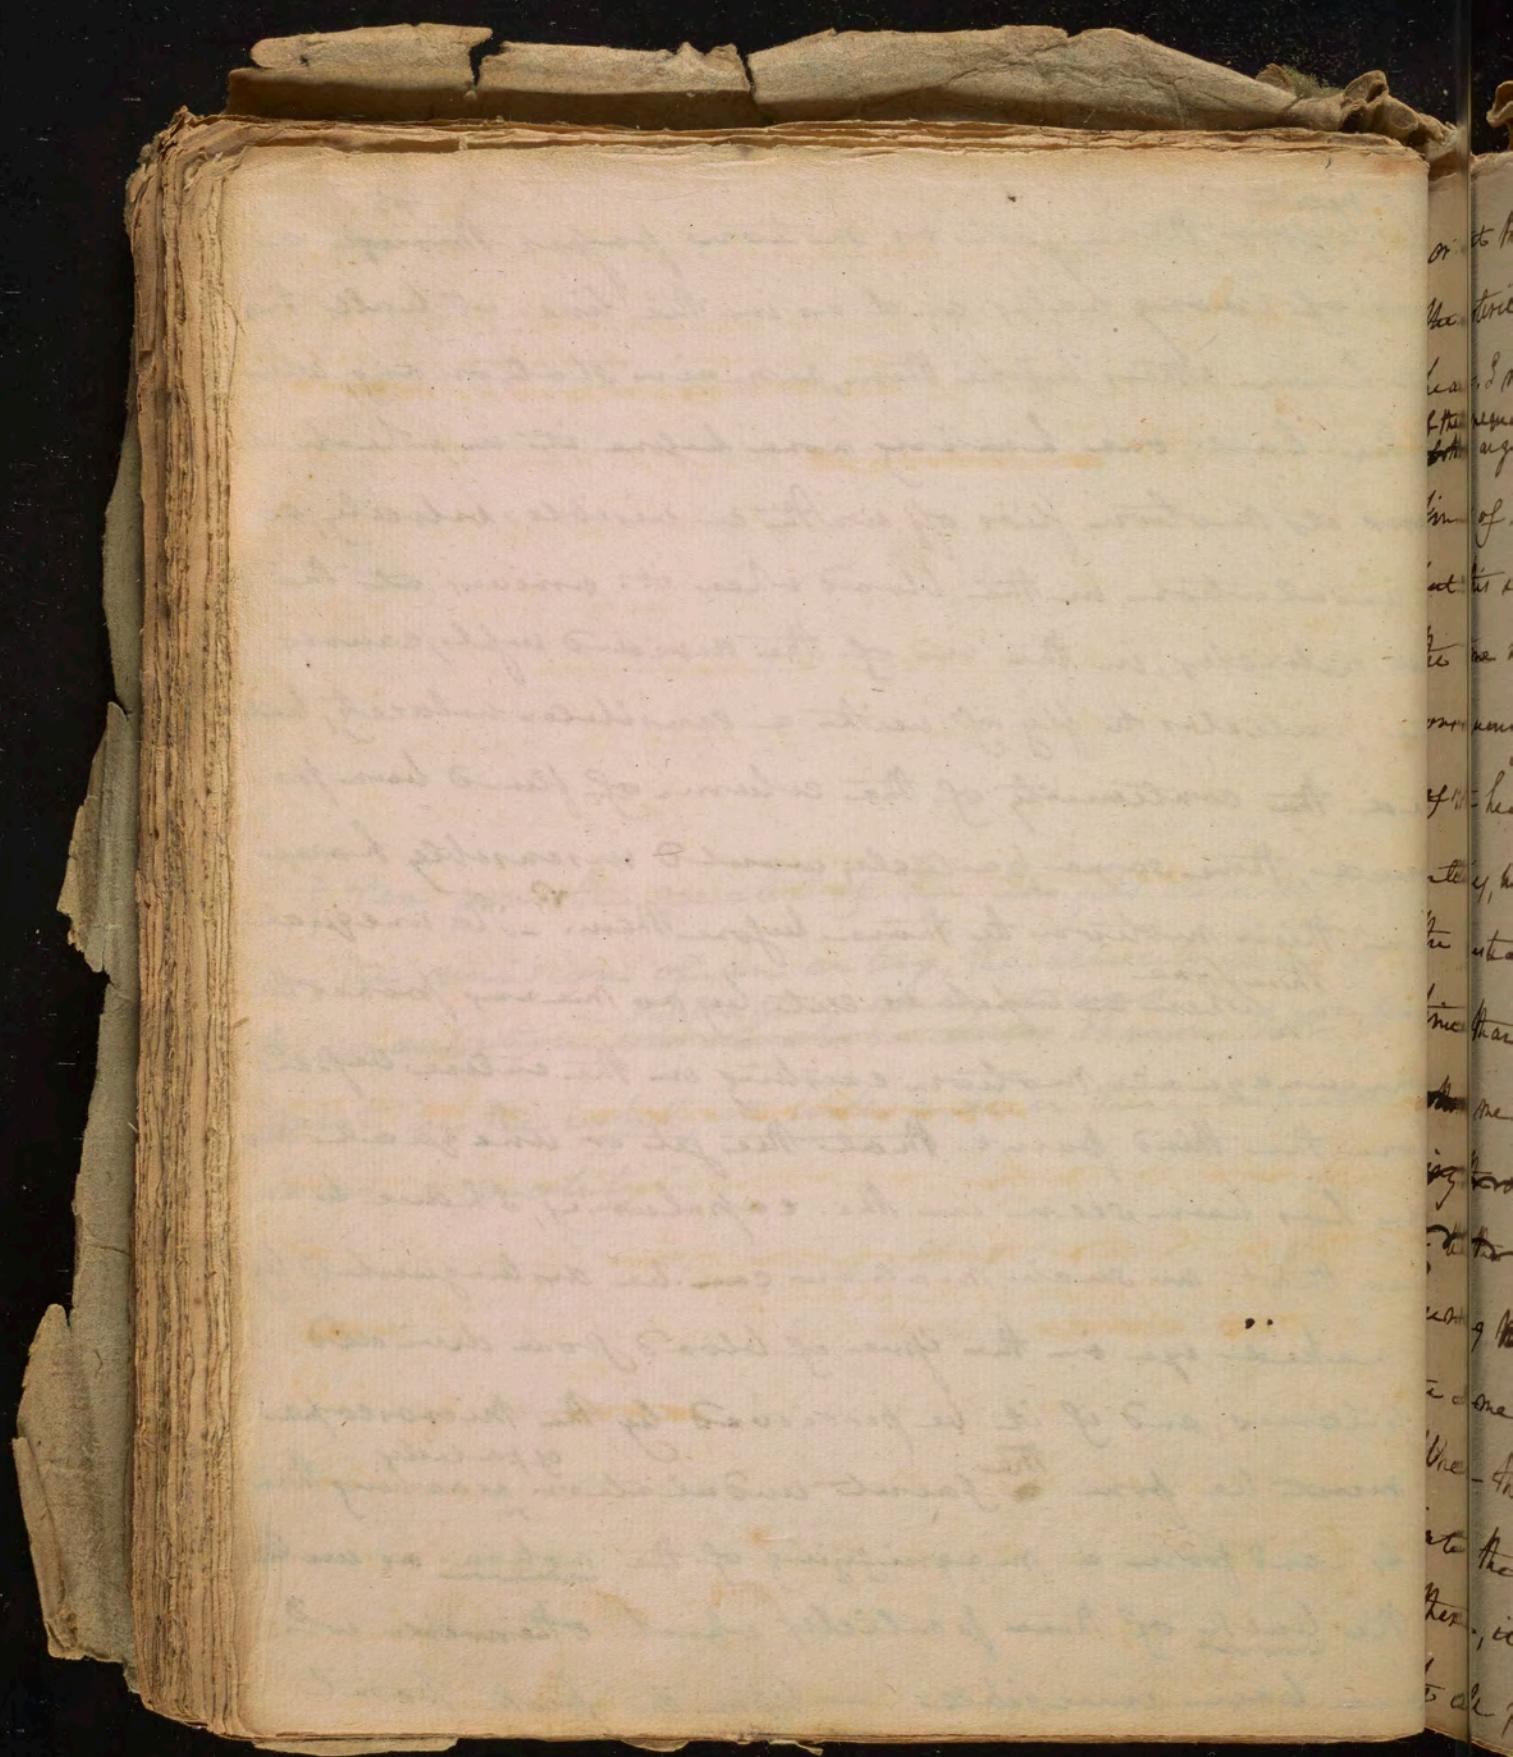

of the auricle must give it a velocity in the way it is beat resisted so that a slight momentum of the blood of the cava will continually carry it into the auricle. - Secondly if the blood of the cava ~~was~~ ^{be} discharged by a jet then all the blood of the veins behind it must also have an alternate retardation and acceleration which we know is not the case. - I conclude therefore that the blood in the arteries does not move by a jetting current. - But I will go further with this question and ask from what facts in the phenomena of the circulation, this supposed alternate quick and slow motion of the blood in the arteries is inferred, - They are these. The sensation of a jerk or pulse in the artery in which it is said the current passes with a greater velocity under the finger. 2^d. The alternate further and nearer jet on the division of an artery. 3^d. The alternate motion said to be seen in the capillaries, and 4th. From the blood being driven into the artery by the heart, in alternate gushes, it is inferred that the same gushing must pervade the ^{whole} arterial course. - In answer to the first I hope I have shown you that the throb felt in the pulse is not produced, by the mass of blood in the vessel

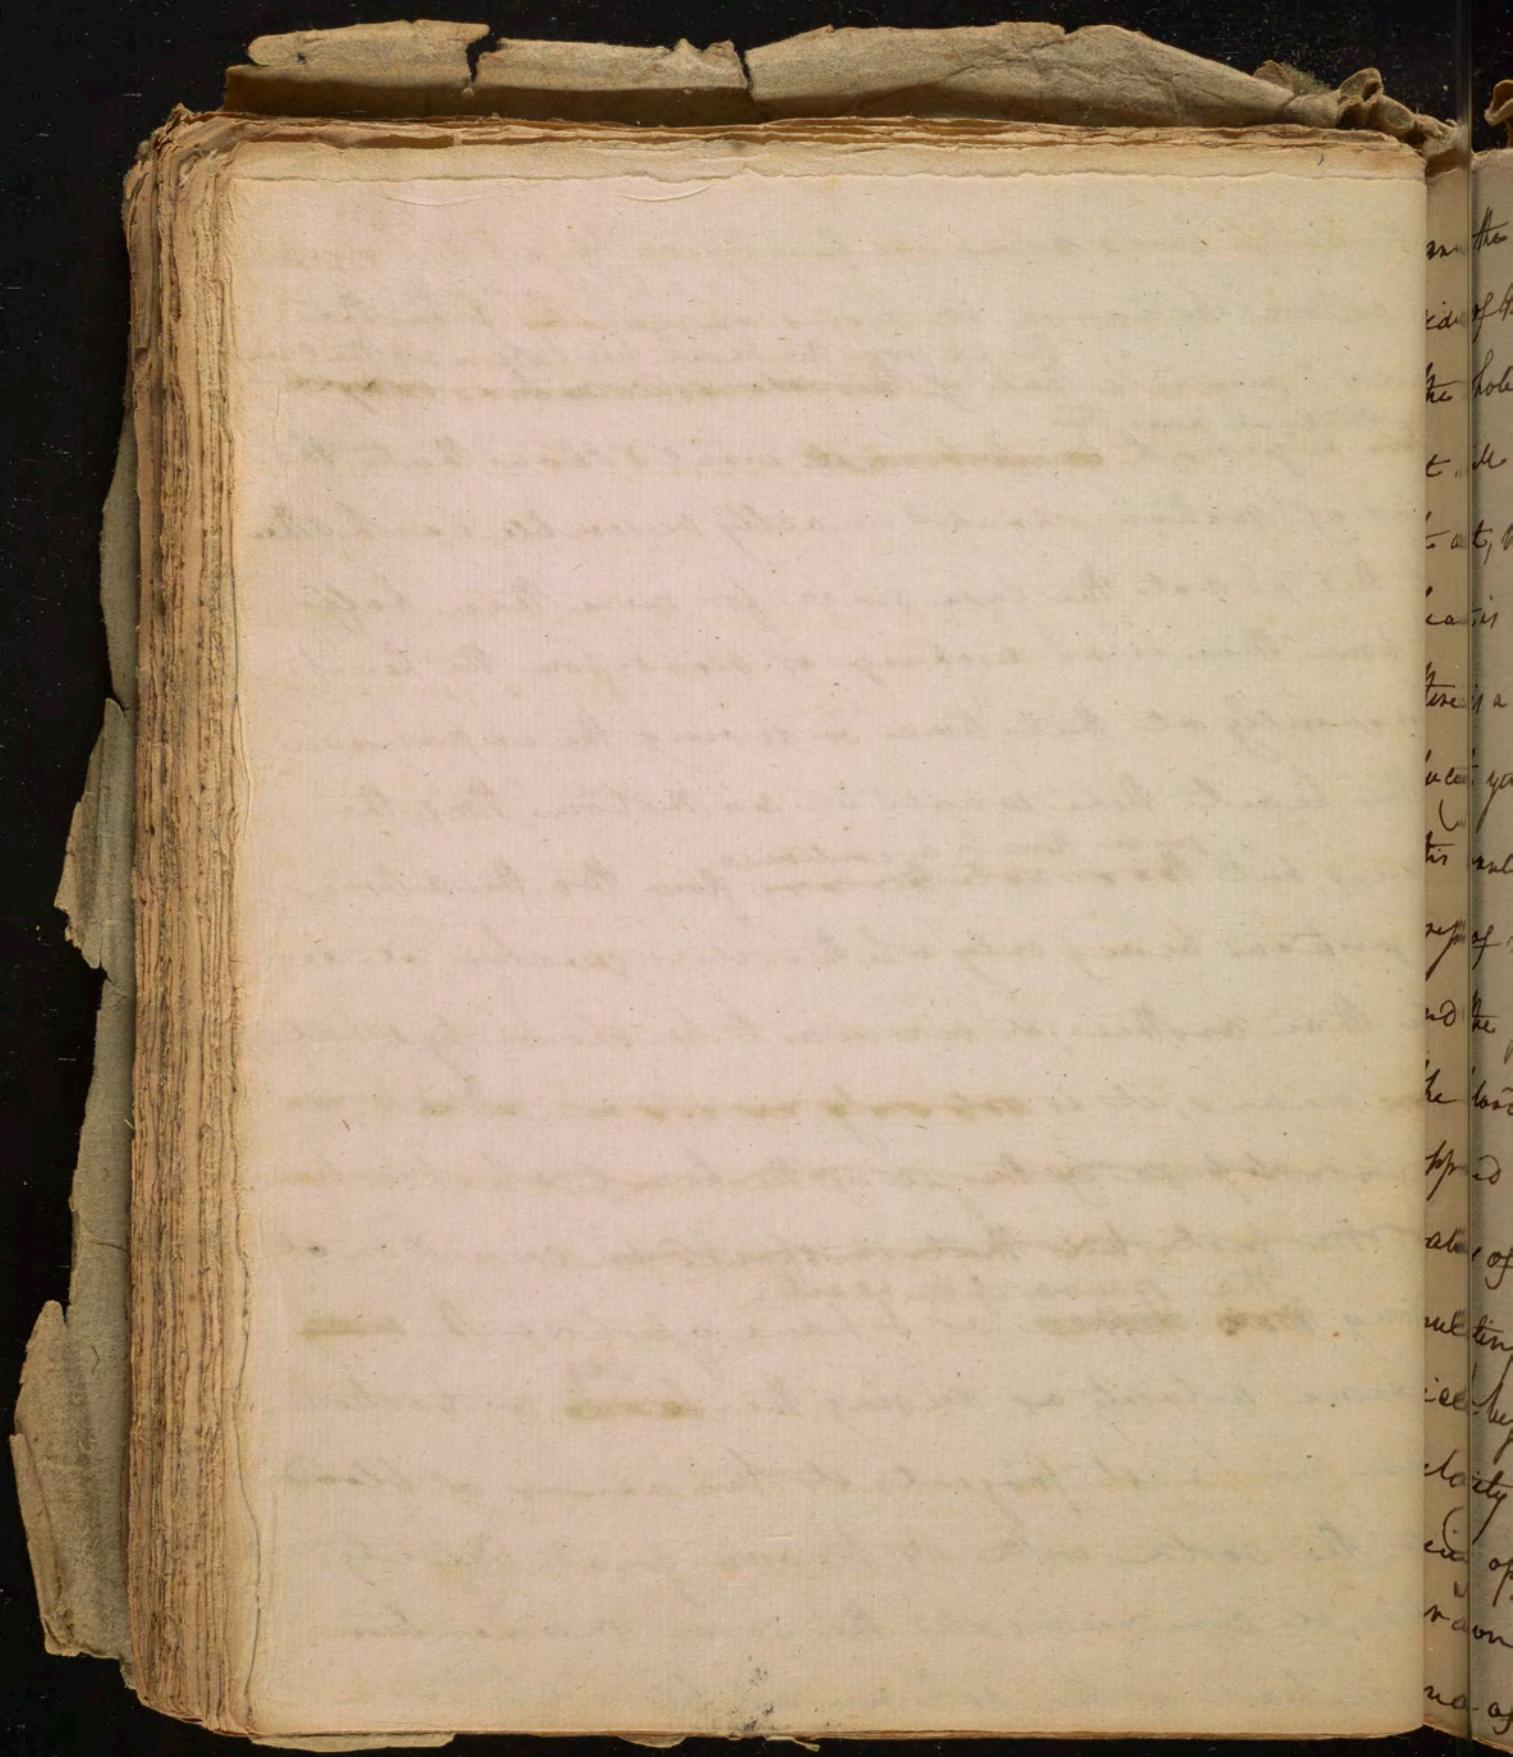

passing quickly under the finger, but by the ⁴⁴ heart or
shock of the sides of the heart on the surface of its
contained blood, sending out an undulation that
in an instant spreads thro' out the system
and to give you a familiar illustration, just as, the
blow or shock given to one side of the abdomen of
a stuporous patient, communicates in an instant
an undulation or pulse to the hand applied to the other
in which case it is certain the mass of the fluid has
not changed its place. - its particles only having
in succession made a thro' infinitely small spaces, and thus
communicated the impulse or shock, precisely as
sound is communicated thro' the air. - With regard
to the second fact it is thought that as the blood
flows from a cut artery, with an alternately quick
or slow leap, ~~and~~ it must necessarily have
the same variable motion within the vessel, but
a little reflection on the phenomena will teach us
that the inference is not ~~fair~~. From what I have said
of the fluid undulations, you have understood, it is
a motion of the particles, communicated to the part

5. & then from the greater of the two jets exhibited
on the emission of an air-bag, the velocity given by
the undulation, ^{the subtracted of course it was} ~~and always happens~~ shown not to
exist in the vessel, it will reduce these impulses
to an equality -

icles ^{next} before them, just as motion passes through a series of iron walls. and as in the line of walls that have others before them, remains stationary, whereas the last one having none before it in which it loses its motion flies off with a visible velocity, so the undulation in the blood when it arrives at the last particle, in the end of the divided vessel, causes these particles to fly off with a sensible velocity, but had the continuity of the column of fluid been preserved, these same particles would insensibly have given their motion to those before them. — ^{the} unequal motion, ^{therefore} when a vessel is cut by no means proves the same unequal motion existing in the entire vessels. Upon the third point that the jet or unequal motion has been seen in the capillaries, I have to answer that no such motion can be distinguished by the naked eye in the issue of blood from divided capillaries, and if it be perceived by the microscope it must be from ^{the} faint undulation or ^{of particles} reaching these vessels — and from a magnifying of the motion as well as the bulk of these particles, which otherwise would have been invisible. — Upon the fourth point

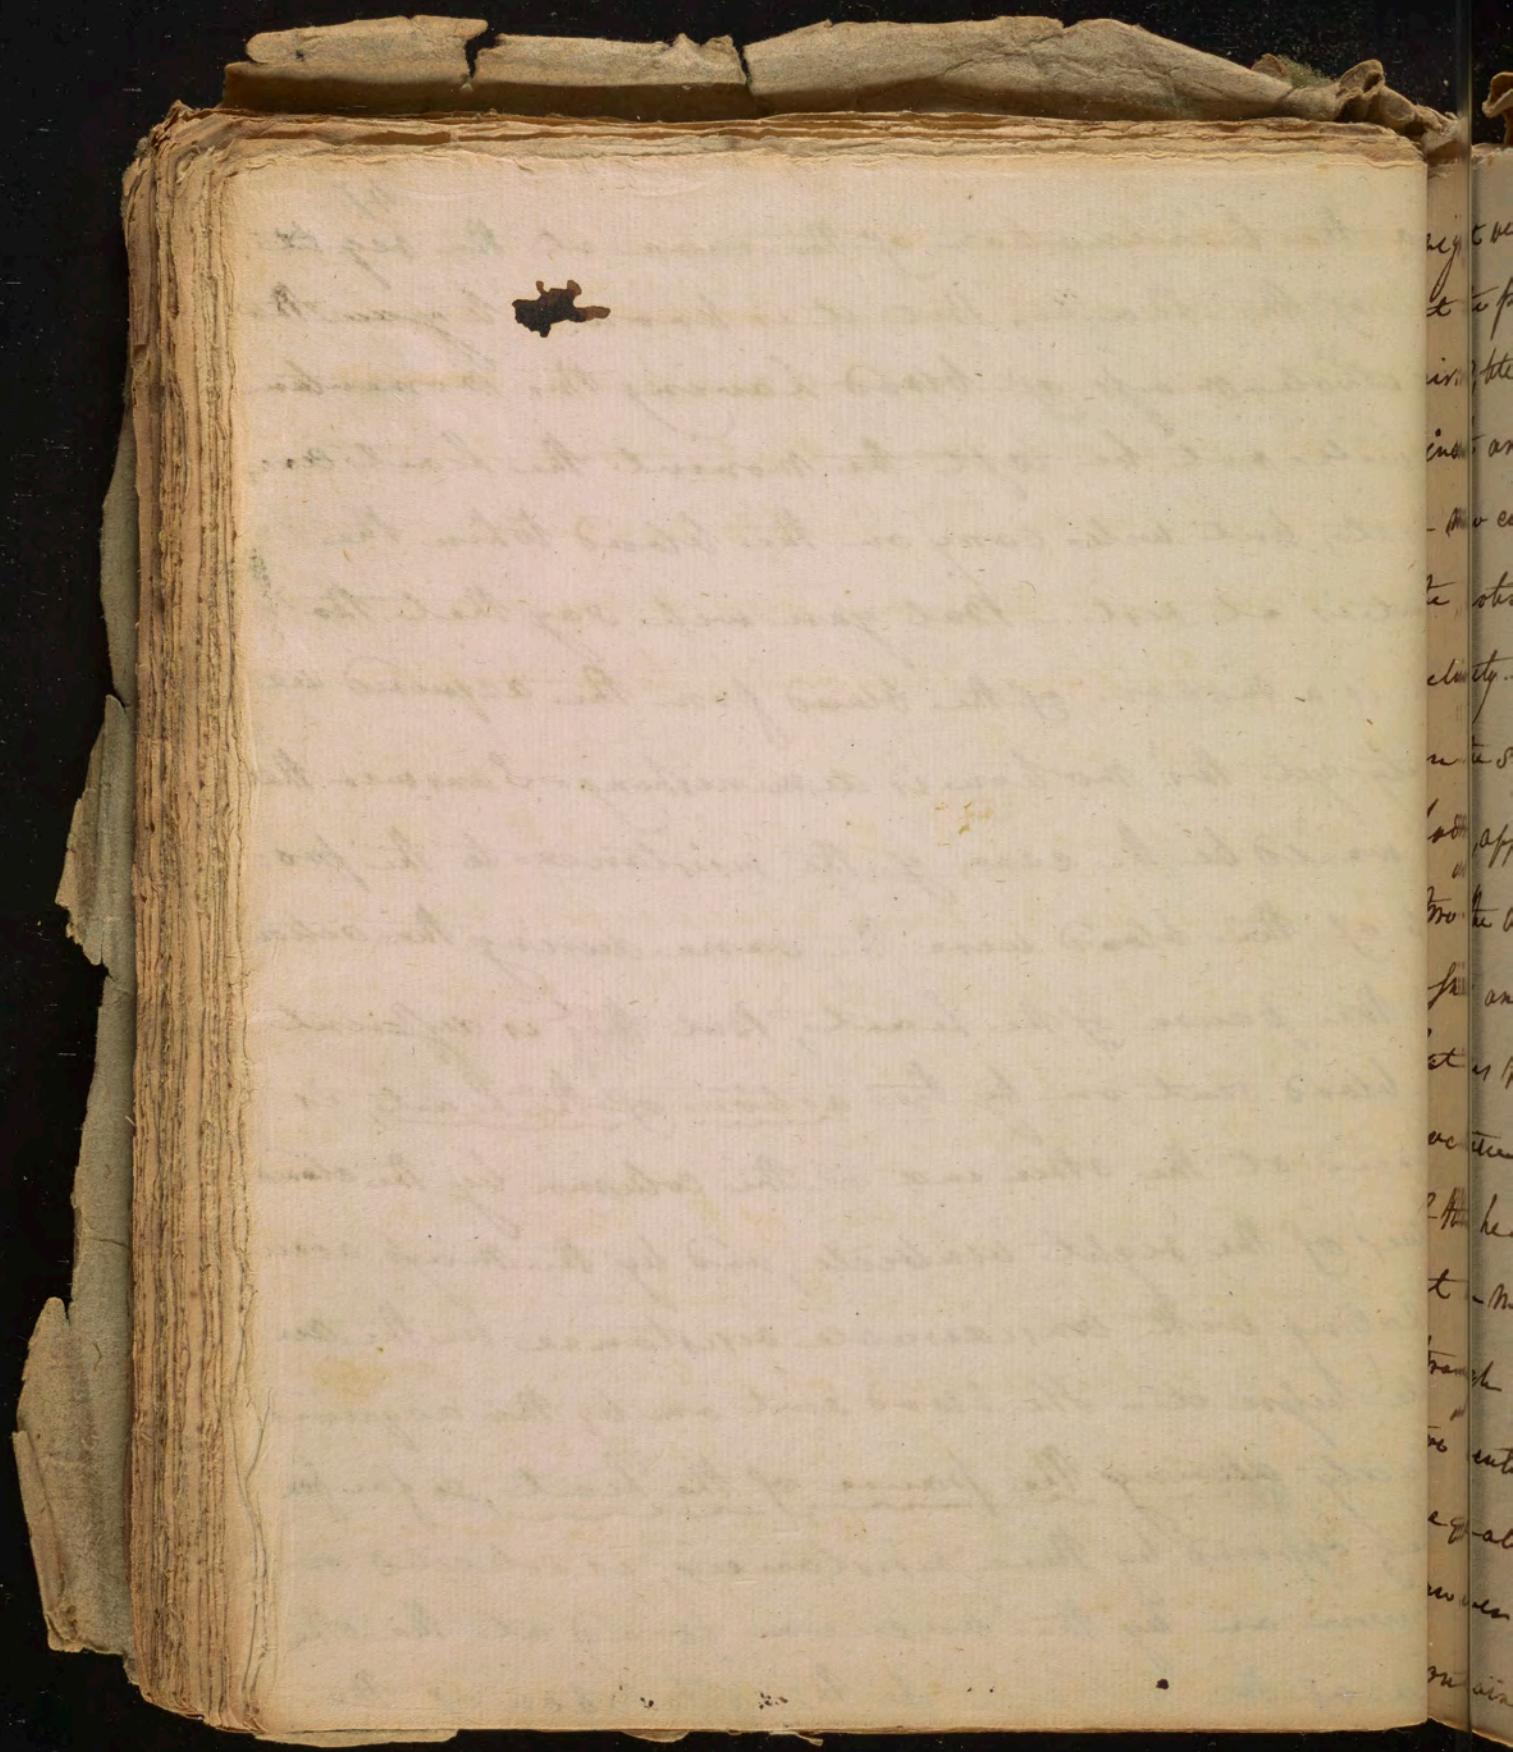

46
or that the blood moves unequally or by jets through
the arteries because it moves unequally from the heart. ^{or by jets} ~~This jet from the heart be taken as the cause of the unequal flow, the argument~~
and it would show that the
kinds of motion should exactly resemble each other.
but this is not the case since for more than half
the time there is no discharge of blood from the heart,
consequently at that time or during the expansion
of the heart there would be no motion thro' the
arteries, but ~~this is not the case,~~ ^{since there is a continuous} flow thro' the arteries,
the question being only whether it is quicker at one
time than another, it remains to be shown by what
~~other~~ means, it is ~~abundantly~~ ^{clearly} carried on ~~at all~~, ^{at}
~~the right~~ ^{the} ~~posterior~~ ^{posterior} page of the jet of the heart, which is known
to be the fact, but ~~that~~ ^{the} ~~it~~ ^{should be} carried on ~~it~~
^{the pause of the heart} during ~~the stops~~ ^{the} as I have observed with ~~any~~
the same velocity as during the ~~long~~ ^{it} contraction.
When the heart projects its two masses of blood
into the aorta with its known great velocity
there, it communicates the same momentum
to all parts of the column of blood between it

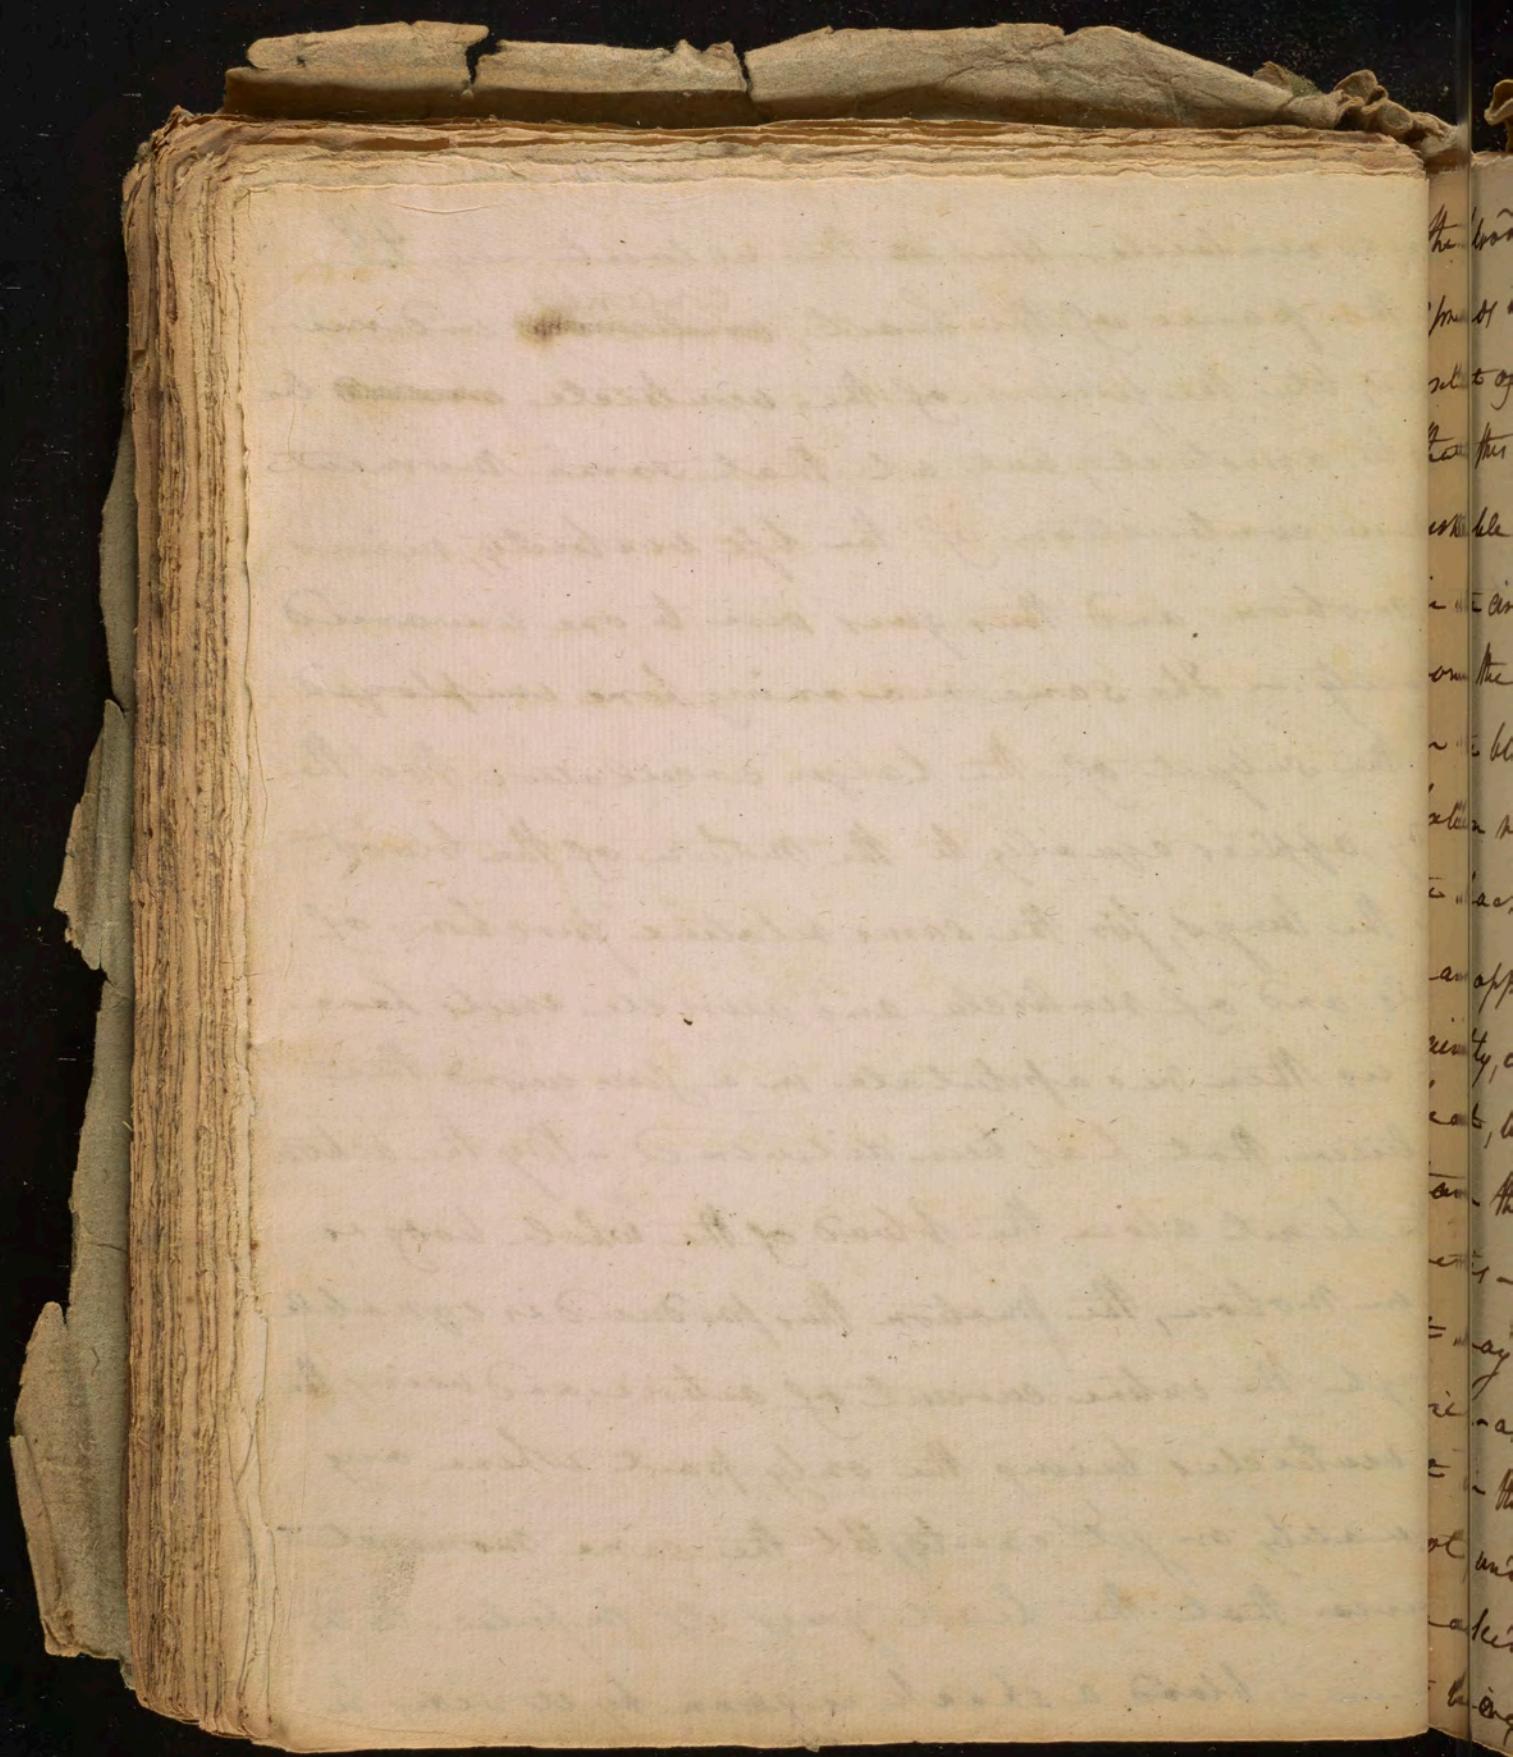

47.

and the termination of the aera at the septal
side of the heart. But it is known to you that
the whole mass of blood having this momentum
it will not be lost the moment the heart ceas-
es to act, but will carry on the blood when the
heart is at rest. — But you will say that tho'
there is a motion of the blood from the acquired ve-
locity yet this motion is diminishing. — I answer that
this would be the case if the resistance to the pro-
gress of the blood were the same during the action
and the pause of the heart, But ~~it~~ is different
the blood sent on by the action of the heart, is
opposed at the other end of the column by the dead
water of the right ventricle, and by the mass accu-
mulating with considerable assistance in the an-
terior ⁵ ~~upper~~ ² ~~upper~~ ³ ~~upper~~ ⁴ ~~upper~~ ⁵ ~~upper~~ ⁶ ~~upper~~ ⁷ ~~upper~~ ⁸ ~~upper~~ ⁹ ~~upper~~ ¹⁰ ~~upper~~ ¹¹ ~~upper~~ ¹² ~~upper~~ ¹³ ~~upper~~ ¹⁴ ~~upper~~ ¹⁵ ~~upper~~ ¹⁶ right ventricle, thus to the velocity acquired ⁴⁸
at the pause of the heart, ~~contains~~ ^{contains} and one-
third, till the filling of the ventricle ~~must~~ be
gives to meet it; but at that same moment
a new contraction of the left ventricle, gives
the motion and thus gives rise to one unvaried
velocity. - The same reasoning here employed
on the subject of the larger circulation thro' the
body, applies equally to the motion of the blood
thro' the lungs, for the same relative proportion of
systole and of ventricle and auricle exists here.
Let us then recapitulate in a few words the
doctrine that has been delivered. - By the action
of the heart alone the blood of the whole body is
put in motion, the motion thus produced is capable
through the entire circuit of arteries and veins, the
two ventricles being the only part where any
inequality or jet exists. At the same moment
however that the heart gives its impulse to its
contained blood, a shock is given by its sides to

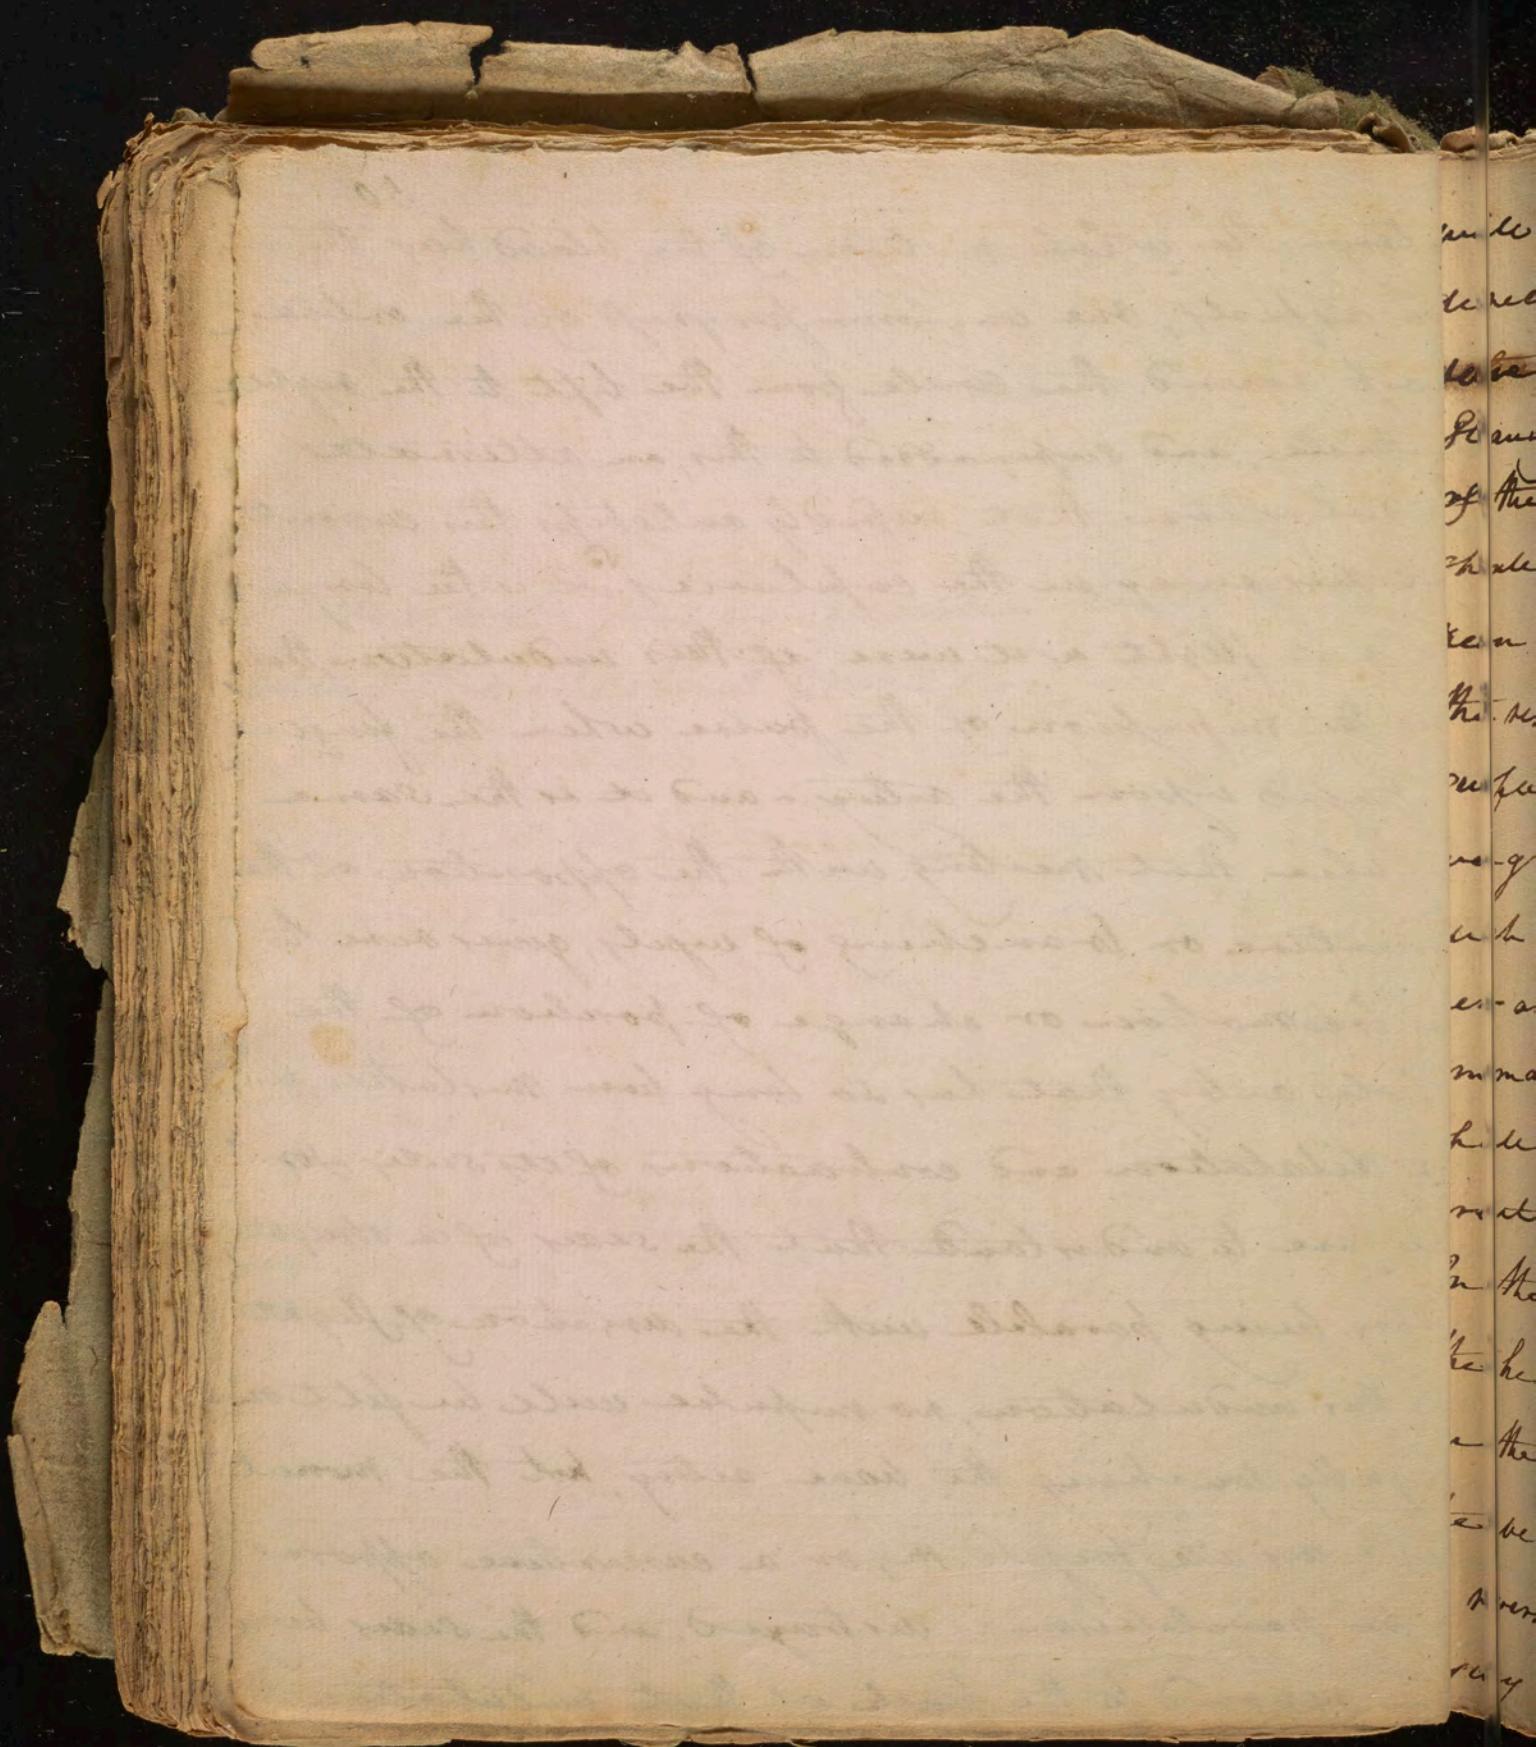

49 ^{which}

the blood that sends out an undulation ~~that~~ spreads in an apparent instant thro' a certain extent of ~~the~~ ^{the} body - for you are to recollect that this undulatory impulse is in its nature perishable after a certain extent, as may be seen in the circles that form on the surface of water from the shock of a stone cast into it, - Now in the blood vessels, the extent to which this undulation reaches will ^{be} measured by the force of the shock given by the heart, In those cases of near approach to death where the heart beats faintly, it is often manifest in the vessels near the heart, but lost in the extremities, tho' it is certain the blood is still flowing thro' these extremities - Again when the heart beats strongly it may reach into and even beyond the capillaries - as observation has frequently detected the jet in the issue of blood from the veins of the foot, under circumstances, as Mr. Hunter has remarked, that did not allow the possibility of its being caused by the pulsation of any contiguous

v. but which gives no sensible velocity to the
blood thro' which it moves -

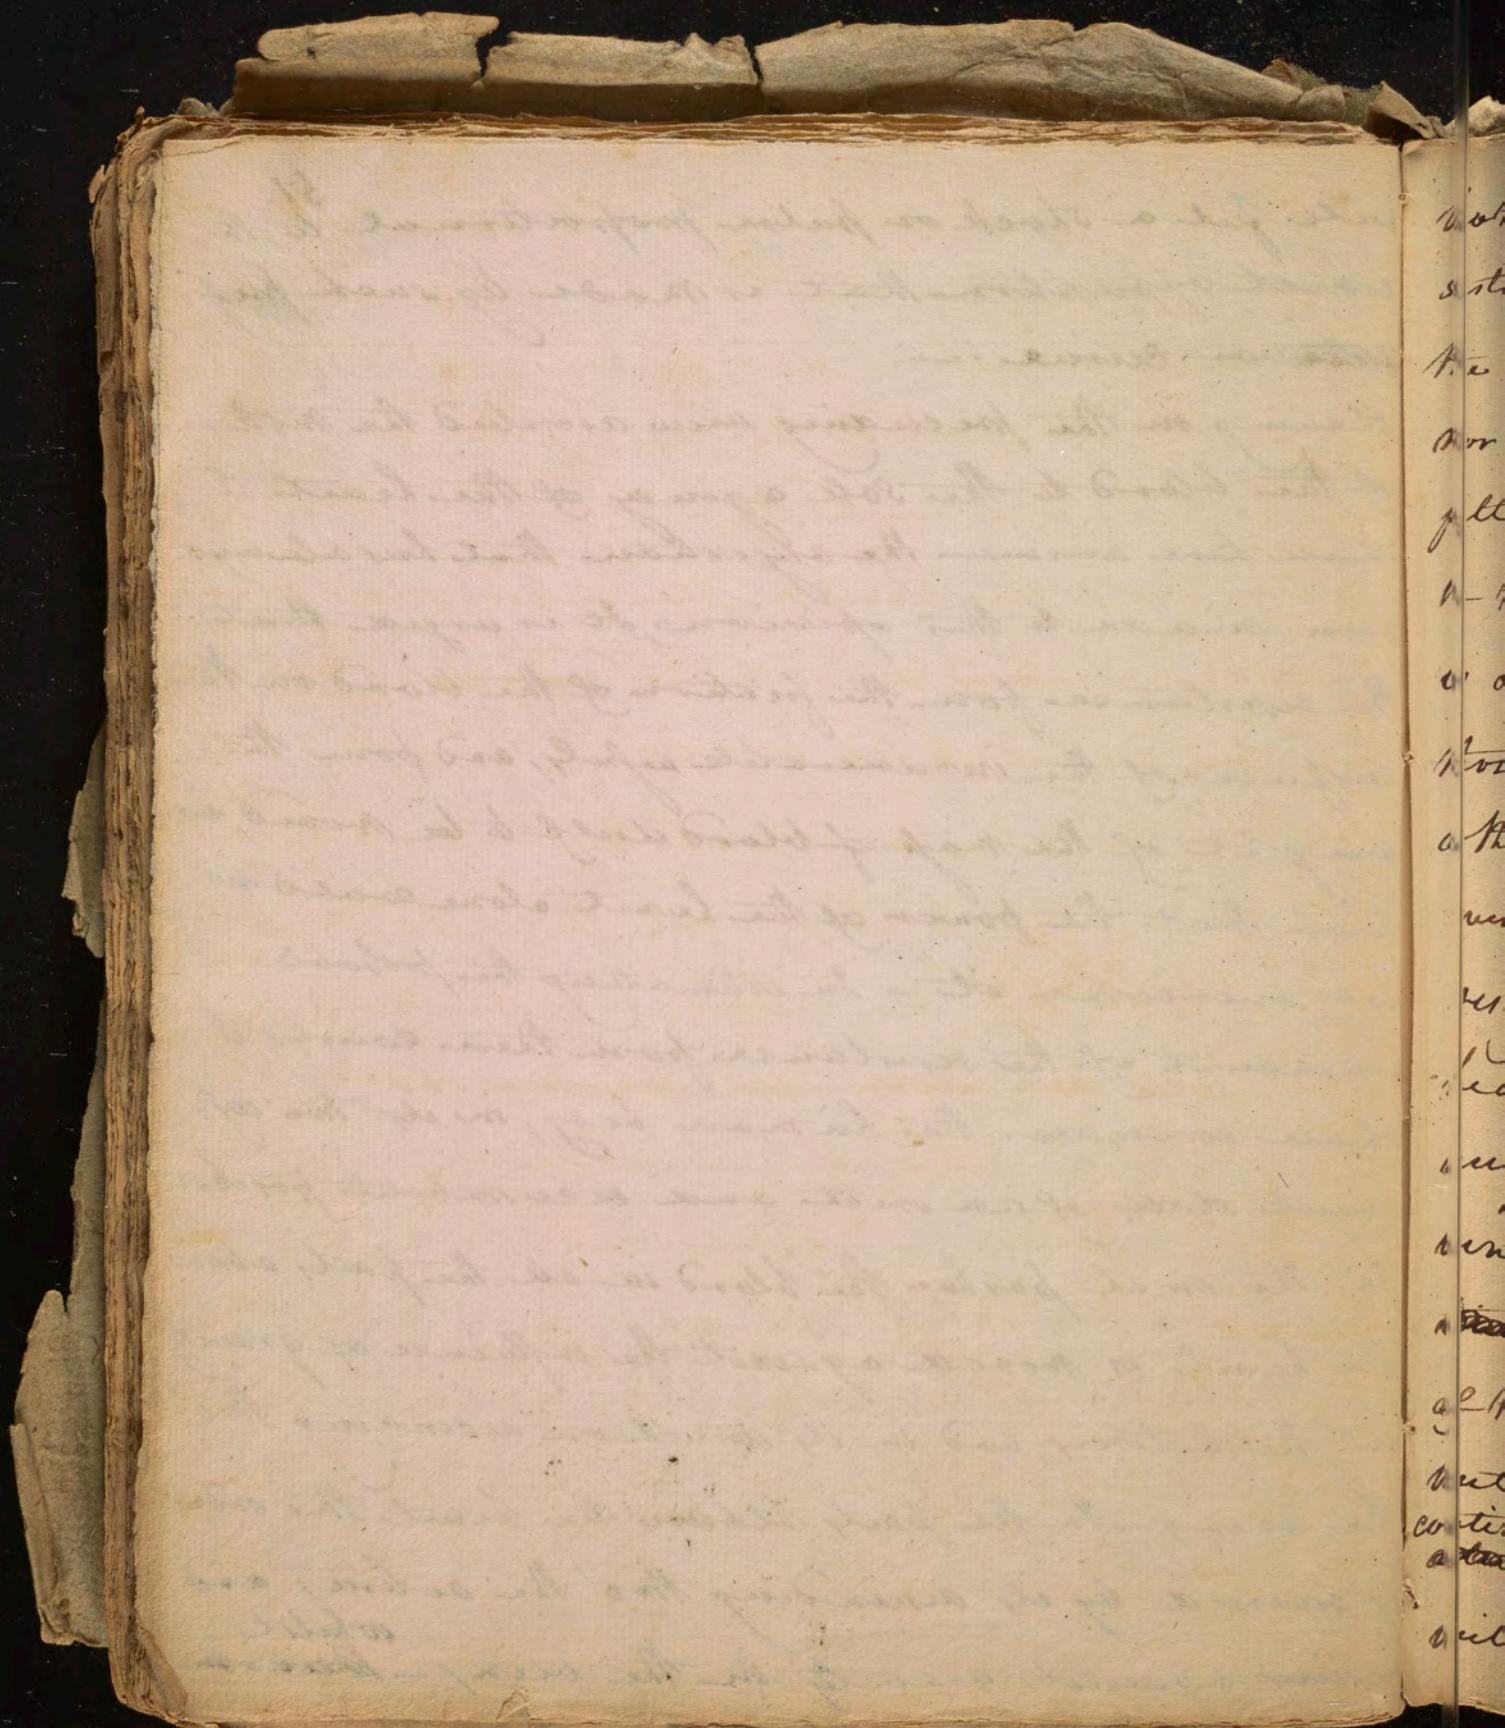

50

artery - The whole motion of the blood has these two aspects, one uniform progress of the entire mass round the circle from the left to the right ventricle, and superadded to this, an alternate undulation that rapidly overdrives this current and dies away in the capillaries. It is the longitudinal flight and wave of this undulation, that gives the impression of the pulse when the finger is press'd upon the artery. - and it is the same impulse that meeting with the opposition of the curvature or branching of vessels, gives rise to the locomotion or change of position of the whole artery that has so long been mistaken for the dilatation and contractions of its sides for you are to understand that the sides of a straight artery being parallel with the direction of flight of this undulation, no impulse will be felt on slightly touching the bare artery, but the moment the sides are press'd in, or a curvature opposes that parallelism is abrog'd, and the sides being now opposed to the track of that undulation

will feel a shock or pulse proportional to the
direct opposition that is made by such pressure
upon the artery. —

Having in the preceding view ascribed the motion
of the blood to the sole agency of the heart I
shall here answer the objection that has always
been made to this opinion, It is urged that
the resistance from the friction of the blood on the
surfaces of the innumerable vessels, and from the
weight of the mass of blood itself to be moved, is
such that the power of the heart alone could ne-
ver overcome it. — In estimating the probable
amount of the resistance from these causes I
shall consider the human body, in its two dif-
ferent states of an erect and recumbent position.
In the erect posture the blood in all the parts above
the heart is moved against the influence of gravity
in the arteries, and in its direction ascending thro'
the veins — In the parts below the heart this order
is reversed by its ascending thro' the arteries and
rising against gravity in the veins — ^{whilst} ~~but in~~

52.

both above and below there is a similar resistance from friction. - But in the parts below the heart, neither the resistance from friction nor the gravitation of the blood in the veins, is felt or to be overcome by the heart. - For since in these parts, the blood in the arteries, and veins is one continuous column, the ~~quantity~~ ^{quantity} of blood in those two sets of vessels would balance each other if the tubes in which they are contained were of equal height, - but the arterial tube rising higher than the entrance of the veins to the heart, and ~~that~~ ^{being} ~~it~~ ^{it} constant by fate, the weight of the arterial will exceed that of the venous stem, consequently there will be a ~~constant~~ sinking of the first and a rising of the last to maintain the equilibrium but the longer stem of the arteries, being continually filled by blood from the heart, there will be a continual rising of the column

Upon the principle here laid down, we may
see a cause of the easy progr^s of the blood
thro' the lengthened, and apparently obstruc-
ting circulation of the lines. —

53.

in the veins simply from the greater weight
of the arterial column. So that the weight of
the blood and the resistance of its friction are
both overcome in these inferior parts, by gra-
vity alone, with no further aid from the heart
than its constantly keeping the higher por-
tion of the arterial stem full. — In the erect
posture therefore the greatest labour of the heart
will be to propel the blood against its gravity
throu' the arteries of the superior parts of the body
and to overcome the resistance of friction there.
Hence we find those animals whose heads are
always or usually carried erect, have the heart
placed near it, whilst those in whom the
head is on the horizontal line, or below it, have
the heart seated near the ~~center~~^{middle} of the whole
length of body. — In the recumbent posture of the
human body the aid that gravity had given
in overcoming the friction of the blood in the
parts below the heart now ceases, and the
whole of this resistance is thrown upon the

54

heart, But it will be seen that tho' the heart
is thus burdened with a new obstruction in
the recumbent posture, it is at the same time
relieved from the labour of sending the blood
against its gravity to all the parts above the
heart. — tho' it still has to encounter its friction
there. — as in this position there is little or no gravity
to overcome it appears that friction alone is the
obstacle to the recumbent circulation, and
whether this or the erect position offers most
resistance to the heart resolves itself into the
question whether the resistance of the gravity
and friction of the blood sent to the parts above the
heart, be greater or less than the friction alone
of the blood sent to all parts of the body. — This
is I believe one of the ~~other~~^{unanswerable} ~~whole~~ questions
of physiology, but it would seem probable
that the resistance of friction ~~throughout~~ the
whole body or the recumbent resistance
was the greater, and that probably from

It appears then that the motion of the blood upon the heart is the principal if not the greatest resistance to the action of the heart. and the question is whether the heart is able to overcome it, now there exist no elements on which a precise calculation can be formed, of the power of the heart and the weight of this resistance, it is impossible therefore to make a strict comparison of them - or to found a judgment immediately upon them, they must then be rejected from the argument, and their relationship sought by more collateral means. - Now since the heart does not a force in circulating the blood - and since no other cooperating cause or cause have ever been shown, the inference in the present state of our knowledge must be drawn that the heart alone is sufficient for that circulation -

55
This case arises the full and slow pulse, and
the frequently obstructed circulation of the
horizontal portion and of sleep. - The effect
of muscular exertion I shall show immediately
but no part in that alteration. -

From the view I have just given of the gra-
vitating influences of the two vascular columns
of blood in aiding the motion of that fluid
in an erect posture, we come to the knowl-
edge of the valves that are placed throughout the
whole greater part of the veins. - The valves have
been supposed to aid in the circulation of
the blood, by relieving the pressure of the column
of blood in the veins, by preventing a regur-
gitation, on any obstruction taking place, or
as they are found in most abundance in the
extremities they were supposed to have an in-
timate reference to the action of the mus-
cles upon the veins. - But these ascribed uses
must be rejected upon an investigation. For

50

since the blood flows uniformly in the veins
the valves must be always open and hence
can oppose nothing to the weight of the col-
umn of blood. - nor can they even be closed
without producing an obstruction and an
accumulation behind which if it continue
any length of time will be back'd to the heart
itself - nor is any thing gained by their presence
under muscular action. - when a vein is press'd
by a muscle the blood is arrested in its passage
thru it, an accumulation takes place behind
which will be the same whether there be no
valves or whether they be innumerable, for
the accumulation takes place not from the
blood press'd backward by the muscle, but
from the fresh streams arising from the
arteries. and the presence of valves can in no
way alter the impetus or quantity of these -
In order to make you sensible of the use -

is the impetus of

57

of the valves it is necessary to recur to the
fact that when the body is erect, the
blood in the arteries and veins forms two up-
right columns communicating ~~at~~ below.
It is plain to you that as these columns of
fluid have considerable weight and mobility
if a shock is given to the body in a vertical
direction, an impetus must be communicated
to those columns which will cause them to
rush on more in that direction with a force
proportioned to the degree of the shock. If then
there were no valves in the veins, and an impe-
tus were given by running leaping or any ver-
tical motion of the body the ordinary and
regular current of the blood would be broken
and impeded by the powerful play of the
motion of these columns. But the column of
fluid in the veins from ~~the~~ ~~property~~ ~~being~~
~~at~~ ~~the~~ ~~end~~ ~~of~~ ~~the~~ ~~body~~, the ~~property~~ ~~in~~
~~as~~ its descent will be against that of the

arterial column and this last being ⁵² en-
creased by the accession of more blood from the
heart, an accumulation would take place
~~injurious~~ ^{injurious} both to its motion and structure -
But let us suppose valves to be placed in the
course of the venous column, and the ^{ascending} ~~in play~~
of this column will be destroyed, while that of
the artery remaining, and far exceeding the ⁱⁿ weight
of the other, the blood will be driven on
with an accelerated velocity up the ^{ascending} ch-
annel of the vein - and this is the reason
that running, leaping, and other successive
violent shocks given to the body are always
attended with an increased circulation -
It is commonly supposed that the muscular
motion producing these exercises is also the
immediate cause of this rapid motion of
the blood - But you can't fail to observe that
whilst muscular action hastens the flow of the
blood between the point of ^{propulsion} and the heart

the blood may elude this internal pressure by another and an external course. The circulation would be more obstructed and carried back in greater quantity on the heart, from the arteries than the veins, if it were true that muscular action has that effect on the motion of the blood which the received theory supposes. From the view I have just given of the use of the valves, their presence in the arteries is altogether unnecessary. —

I have then gentlemen endeavoured to set before
you what I will not call a theory of the circulation
for your reflections, but a display and arrangement
of its phenomena for ~~you~~ the test of your future ob-
servation and experiment, I would not wish
so far to change the duties of pupil and teacher
as merely to the orage for you, an employment
in which the Master is ever inferior to the
scholar. Nor would I willingly be guilty of the
high crime in science of offering to you ^{my more} ~~more~~ ^{the}

it does at the same time retard the flow ⁵⁹ behind
from the point of pressure to the arteries - so that
on the whole there could be no gain of velocity,
and this is conformable to fact, for where mus-
cular action alone takes place, as in many
convulsive diseases, the pulse is never acc-
elerated to the degree that those other causes
produce, it is commonly but little retarded above
standard frequency, and sometimes reduced much
below it - The valves therefore are not adapted
to any use in a quiet state of the body
and were it never exposed ^{from shocks,} to the kind of
motion I have spoken of, they would be all-
together superfluous. — According to the doctrine
of the valves usually received they would be as necessary
to the proper function of the arteries as the veins - for
notwithstanding the arteries are more rigid than the
veins and capable of resisting greater pressure, still this
greater resistance is as nothing to the strong pressure of
the muscles which surround them, and since there
are no superficial arteries ^{vi.} as there are veins, by which

gination on those points that promise an
intervisible difference of opinion, a crime
to which ~~that~~ other persons and times will be sure to
adjure the mortifying penalty of oblivion. —
If you wish to accumulate knowledge or
fame, keep your unweary attendance in
the school of observation and experiment —
~~but~~ ^{yet} if you must sometimes play the troubadour
of science, go to the subjects of the Brain, of
Generation, and animal life, and exercise
on them the pastime fancies of a fabulist.
But other points of physiology that like the
circulation are palpable and submitted to
philosophical enquiry, demand a more manly
exertion of intellect. —

James Rush

Philadelphia

September 1811.
